Drug Hearings . .
Social Security Expansion . .
Labeling Bill . .
Medical School Grants . .

PHYSICIANS' COOPERATION CITED AT DRUG HEARINGS

The role of the American Medical Association in cooperating with congressional investigations of the drug industry and A. M. A. standards on drug advertising were both challenged and defended at the current Senate inquiry on drug prices.

Although most of the testimony at the sessions of the Senate anti-trust subcommittee headed by Sen. Estes Kefauver (D., Tenn.) dealt with drug prices, there was some discussion of advertising and the A. M. A.

The most controversial charge was leveled by Rep. John Blatnik (D., Minn.), who led a House government operations subcommittee investigation of drugs two years ago. Mr. Blatnik, testifying before the Senate group, contended that the A. M. A.'s attitude was "[illegible]." In a press release he said medical [illegible]" the probe "at every turn."

In reply, the A. M. A. issued a statement asserting that the charge was "completely untrue."

The statement continued, "A representative of the A. M. A. testified before the subcommittee. In all of the subcommittee hearings the A. M. A. cooperated fully. Correspondence in our files documents this cooperation in the form of thank-you letters from Congressman Blatnik and staff. The A. M. A. has been fighting false and misleading drug advertisements for over 50 years, long before the government operations subcommittee even existed."

Senator Kefauver made it clear that as far as the present investigation was concerned he did not share Representative Blatnik's views. The A. M. A. has "cooperated fully," he said, adding that the organization should be congratulated on its aims and objectives which include "fair advertising and the best medication for the people of the United States."

The senator said he wanted to "make it very clear" that the subcommittee's relations with the A. M. A. have been "very pleasant," that there had been no difficulty at all in such dealings, and that the organization and physicians across the country have "exhibited extreme interest" in the subcommittee's goals.

Although Blatnik had critical words for the medical profession, he departed from his prepared statement to make this assertion:

"It is not made quite clear in this summary statement, but there is some very fine work done within the medical profession itself. Practically all, certainly most of the professional journals screen the advertising which they accept. Some even have medical boards that will process and screen all advertising of so-called ethical drugs and will accept only a high-grade type of advertising as a degree of modesty with their claims and yet accuracy, advertising bona fide legitimate, well-established and recognized ethical drugs."

The hearings thus far have concentrated on makers of steroid drugs and tranquilizers. In February, the subcommittee was slated to call Dr. Austin Smith, president of the Pharmaceutical Manufacturers Association, and other witnesses to testify on the general subject of drug prices. Kefauver has maintained that the prices are too high, but industry witnesses have pointed out the high risks of the business, the large sums needed for research, and the comparatively recent growth of the ethical drug industry since World War II.

ADMINISTRATION STUDYING SOCIAL SECURITY EXPANSION

President Eisenhower said, at his weekly news conference, that the administration has under consideration a plan to boost social security benefits for elderly beneficiaries. However, the Chief Executive emphasized, "There has been no conclusion reached in the administration; I have not yet made any recommendation on it."

A reporter, noting that "there seems to be considerable pressure in Congress for amending the Social Security Act this year," asked if the administration is planning to propose any changes.

Mr. Eisenhower replied, "Well, there is under. . . . there is under consideration a possible change to run up the taxes by a quarter of 1% to take greater care, make greater provision for the care of the aged."

This would be the same increase called for in the Forand proposal to broaden the social security system to provide for some federal financing of health care for the beneficiaries, a bill that opponents assert would be the first step toward complete government control of medicine.

Mr. Eisenhower did not indicate what type of "care" was involved in the proposal being studied in high administration circles. Arthur S. Flemming, Secretary of Health, Education, and Welfare, has promised that the administration would come up this year with a "positive" program for helping the elderly meet their medical and health bills.

Meanwhile, backers of the controversial Forand legislation have pressed their drive for congressional enactment. The AFL-CIO, prime proponents of the bill that was vigorously opposed by the administration, urged a letter-writing campaign b all members of the federation to the congressm who make up the House Ways and Means Comr tee that has original jurisdiction over the mea

SENATE URGED TO KEEP LABELING BILL STRONG

The American Medical Association asked the Senate Commerce Committee to reject recommendations to weaken the measure calling for precautionary labeling of household substances that might cause harm if consumed or ignited.

In a letter to the Committee, Dr. F. J. L. Blasingame, A. M. A. Executive Vice-president, opposed a suggestion to omit toxicological tests in determining the necessity of the signal word "danger" and to apply the term only to highly toxic substances which would also be labelled "poison."

This would "seriously dilute the effectiveness of the proposed legislation," said Dr. Blasingame. "The American Medical Association does not believe that these recommendations are sound. Objection to toxicity standards, because they overtax testing facilities, is a recurring but unfounded fear. This fear has been expressed during the consideration of every legislative improvement in the regulation of chemicals" since 1927, said Dr. Blasingame. "Admittedly, the provisions of S. 1283 [the labeling bill] would require more toxicity testing than has heretofore been undertaken for these products. However, improved protection for consumers against bodily injury necessitates and justifies the additional work. In addition, experience with older laws indicates that the economics of the problem will insure facilities and personnel to meet the demand. We strongly recommend maintaining the toxicity standards for 'danger' set forth in S. 1283. . . ."

The A. M. A. official also objected to a proposal to limit the scope of the measure to substances "suitable for household use," rather than "distributed as packaged chemicals for nonmanufacturing purposes." This would cause the same "inherent weakness" now found in the Federal Caustic Poisons Act, and "to continue it under the guise of new and improved legislation is hardly a step forward and certainly will not meet the compelling need for better control of hazardous substances," said Dr. Blasingame.

The measure before the Committee, headed by Sen. Warren Magnuson (D., Wash.), would replace existing statutes and provide broader coverage of products requiring labeling as well as more detailed labeling requirements. Since the present federal labeling law was enacted in 1927 for poisonous substances, many new compounds for household, commercial, and industrial use have been introduced which are not covered.

BROADER MEDICAL SCHOOL GRANTS ASKED

Arthur C. Flemming, Secretary of Health, Education, and Welfare, proposed legislation to provide broader grants to medical, dental, and public health schools for medical and health-related research and research training programs.

In letters to the President of the Senate and the peaker of the House, Flemming asked that the blic Health Service Act be amended to give .U. S. Surgeon General authority to make grants he general support of the research programs of institutions, as well as the grants now authorized to support specific projects proposed by individual applicants.

Funds for the general grants would come from a uniform percentage, not to exceed 15%, of the appropriations to the National Institutes of Health for research grants authorized in existing legislation.

"The establishment of a program of institutional research grants which would be possible under this legislation will carry into effect recommendations made to the HEW Secretary by a distinguished group of consultants who have studied problems of medical research and education under the chairmanship of Dr. Stanhope Bayne-Jones," Flemming said.

The Bayne-Jones committee has said, "An increase in the capacity of research and educational institutions to perform their educational and research functions more effectively would be in the national interest. To this end, federal funds for research should be provided under conditions which give the institutions a substantial degree of freedom in deciding how to use the funds."

President Eisenhower's Science Advisory Committee also recommended that "institutional grants for specialized fields is another instrumentality [in addition to project grants and program grants] that should be encouraged" in providing support of government-sponsored research in nongovernmental installations.

Flemming pointed out that funds made available for the support of research projects by the National Institutes of Health have risen from a level of $3,500,000 in fiscal year 1947 to a total of 200 million dollars in fiscal year 1960. These funds have been in the form of support for specific projects proposed by individual research investigators working in research laboratories, hospitals, medical schools, and other institutions.

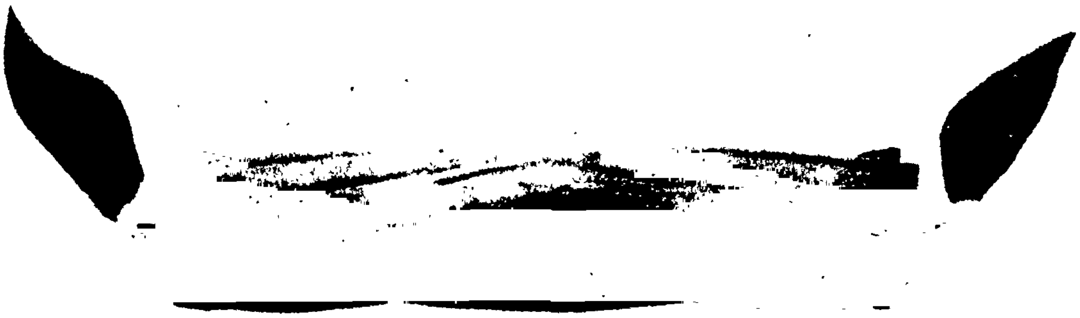
"In large part, the support of research exclusively through the project system has deprived educational institutions of a large measure of autonomy and freedom in determining the character and direction of their research activities," Flemming said. "Furthermore, exclusive reliance on the project system does not make it possible for educational institutions to assume a position of responsibility in carrying out their role in the conduct of medical and health-related research supported through federal funds."

MISCELLANY

The number of resident patients in federal mental hospitals dropped for the fourth consecutive year in 1959. The 542,721 patients in 277 mental hospitals at the end of the year was 2,142 less than in 1958. Dr. Robert H. Felix, director of the National Institute of Mental Health, credited the decline to improved treatment, a basic change in the philosophy of hospital administration and treatment, and a change in the public attitude toward mental illness.

The U. S. Bureau of Narcotics reported there were 45,391 active drug addicts in the United States as of Jan. 1, with the state of New York leading the country with 20,732 addicts. California was second with 6,471 addicts, and Illinois was third with 6,191 addicts.

When the vagus burns at both ends



Pro-Banthīne® with Dartal® moderates both mood and gastrointestinal spasm

The slow simmer of anxiety frequently causes kindred gastrointestinal overactivity. The spasticity and the accompanying distress of excess acid lead to loss of efficiency. Patients subject to such psychoenteric upsets require therapy to calm both ends of the vagus.

Pro-Banthīne with Dartal contains two agents required for such dual therapy: Pro-Banthīne to control and curtail the flare-ups of spasm, excess acidity and excess motility, and Dartal to smother simmering anxiety and tension.

Pro-Banthīne with Dartal contains 15 mg. of Pro-Banthīne (brand of propantheline bromide) and 5 mg. of Dartal (brand of thiopropazate dihydrochloride) in each tablet.

Dosage: One tablet three times a day.

American Gastroscopic Society, Roosevelt Hotel, New Orleans, Mar. 30. Dr. Arthur M. Olsen, Mayo Clinic, Rochester, Minn., Secretary-Treasurer.

American Laryngological Association, Deauville Hotel, Miami Beach, Fla., Mar. 18-19. Dr. Lyman Richards, Massachusetts Institute of Technology, Cambridge 39, Mass., Secretary.

American Laryngological, Rhinological and Otological Society, Inc., Deauville Hotel, Miami Beach, Fla., Mar. 15-17. Dr. C. Stewart Nash, 708 Medical Arts Bldg., Rochester 7, N. Y., Secretary.

American Otological Society, Deauville Hotel, Miami Beach, Fla., Mar. 13-14. Dr. Lawrence R. Boies, University Hospital, Minneapolis 14, Minn., Executive Secretary-Treasurer.

American Otorhinologic Society for Plastic Surgery, Inc., Deauville Hotel, Miami Beach, Fla., Mar. 6-13. Dr. Joseph G. Gilbert, 75 Barberry Lane, Roslyn Heights, N. Y., Secretary.

American Psychosomatic Society, Sheraton-Mount Royal Hotel, Montreal, Mar. 26-27. Miss Joan K. Erpf, 265 Nassau Rd., Roosevelt, N. Y., Executive Assistant.

American Radium Society, Caribe Hilton Hotel, San Juan, Puerto Rico, Mar. 17-19. Dr. Robert L. Brown, Robert Winship Clinic, Emory University, Atlanta 22, Ga., Secretary.

Association of Clinical Scientists, DeWitt Clinton Hotel, Albany, N. Y., March 3-5. Dr. Robert P. MacFate, 54 W. Hubbard St., Chicago 10, Secretary.

Intermountain Pediatric Society, Stardust Hotel, Las Vegas, Nev., Mar. 28-29. Dr. Joseph R. Newton, 2000 S. 9th East, Salt Lake City, Utah, Publicity Chairman.

Missouri State Medical Association, Sheraton-Jefferson Hotel, St. Louis, Mar. 13-16. Mr. T. R. O'Brien, 634 N. Grand Blvd., St. Louis 3, Executive Secretary.

National Health Council, National Health Forum, Miami, Fla., Mar. 13-18. Mr. Philip E. Ryan, 1790 Broadway, New York 19, Executive Director.

National Multiple Sclerosis Society, New York City, Mar. 8. Mr. Donald Vail, 257 Fourth Ave., New York 10, Secretary.

Neurosurgical Society of America, Del Monte Lodge, Calif., Mar. 30-Apr. 2. Dr. Raymond K. Thompson, 803 Cathedral St., Baltimore 1, Secretary.

New Orleans Graduate Medical Assembly, Roosevelt Hotel, New Orleans, Mar. 7-10. Miss Irma B. Sherwood, 1430 Tulane Ave., New Orleans 12, Executive Secretary.

Southeastern Surgical Congress, Roosevelt Hotel, New Orleans, Mar. 21-24. Dr. B. T. Beasley, 1032 Hurt Bldg., Atlanta 3, Ga., Executive Secretary.

Southwestern Society for Nuclear Medicine, Menger Hotel, San Antonio, Texas, Mar. 26-27. Dr. N. T. Werthessen, Southwest Foundation for Research and Education, R. R. 4, Box 86, San Antonio 7, Texas, Program Chairman.

Southwestern Surgical Congress, Riviera Hotel, Las Vegas, Nev., Mar. 28-31. Miss Mary O'Leary, 1213 Medical Arts Bldg., Oklahoma City, Okla., Executive Secretary.

April

Alabama, Medical Association of the State of, Admiral Semmes Hotel, Mobile, Apr. 21-23. Mr. W. A. Dozier Jr., 19 S. Jackson St., Montgomery 4, Executive Secretary.

American Academy of Neurology, Eden Roc Hotel, Miami, Fla., Apr. 25-30. Mrs. J. C. McKinley, 4307 E. 50th St., Minneapolis 17, Executive Secretary.

American Association for the Advancement of Science, Section on Medical Sciences, Vanderbilt University, Apr. 18-19. Dr. George R. Meneely, Vanderbilt University School of Medicine, Nashville 5, Tenn., Chairman.

American Association of Anatomists, Statler-Hilton, New York City, Apr. 11-16. Dr. Louis B. Flexner, Dept. of Anatomy, School of Medicine, Univ. of Pa., Philadelphia 4, Secretary-Treasurer.

American Association of Immunologists, Chicago, Apr. 11-15. Dr. Calderon Howe, Columbia Univ. College of Physicians and Surgeons, New York 22, Secretary-Treasurer.

American Association of Pathologists and Bacteriologists, Hotel Peabody, Memphis, Tenn., Apr. 28-30. Dr. Russell L. Holman, Dept. of Pathology, L. S. U. School of Medicine, New Orleans, La., Secretary.

American Association of Railway Surgeons, Drake Hotel, Chicago, Apr. 7-9. Mr. Chester C. Guy, 5800 Stony Island Ave., Chicago 37, Executive Secretary.

American College Health Association, Toronto, Canada, Apr. 27-30. Dr. Norman S. Moore, Cornell University, Gannett Clinic, Ithaca, N. Y., Secretary Treasurer.

American College of Obstetricians and Gynecologists, Netherland Hilton Hotel, Cincinnati, Apr. 2-6. Mr. Donald F. Richardson, 79 W. Monroe St., Chicago 3, Executive Secretary.

American College of Physicians, Mark Hopkins & Fairmont, San Francisco, Apr. 4-9. Mr. E. R. Loveland, 4200 Pine St., Philadelphia 4, Executive Secretary.

American College of Surgeons, Sectional Meeting, Hotel Leamington, Minneapolis, Apr. 11-13. For information write: Dr. H. P. Saunders, 40 E. Erie St., Chicago 11.

American College of Surgeons, Sectional Meeting, Kahler Hotel, Rochester, Minn., Apr. 14. For information write: Dr. H. P. Saunders, 40 E. Erie St., Chicago 11.

American College of Surgeons, West Virginia Chapter, The Greenbrier, White Sulphur Springs, W. Va., Apr. 1-2. Dr. Ray E. Burger, Grace Hospital, Welch, W. Va., Vice-President.

American Dermatological Association, Inc., Boca Raton Hotel, Boca Raton, Fla., Apr. 8-12. Dr. Wiley M. Sams, 308 Ingraham Bldg., Miami 32, Fla., Secretary.

American Physiological Society, Chicago, Apr. 11-15. Ray G. Daggs, D.Sc., 9650 Wisconsin Ave., Washington 14, D. C., Executive Secretary.

American Proctologic Society, Shamrock Hilton Hotel, Houston, Texas, Apr. 25-27. Dr. Norman D. Nigro, 10 Peterboro, Detroit 1, Secretary.

American Public Health Association, Southern Branch, Memphis, Tenn., Apr. 13-15. Dr. L. M. Graves, Shelby County Health Department, Memphis, Tenn., Chairman, Local Arrangements, Committee.

American Society for Artificial Internal Organs, Pick-Congress Hotel, Chicago, Apr. 10-11. Dr. Charles K. Kirby, 3400 Spruce St., Philadelphia 4.

American Society of Biological Chemists, Inc., Chicago, Apr. 11-[illegible]. Dr. Frank W. Putnam, Dept. of Biochemistry, Univ. of Florida, Gainesville, Secretary.

American Society for Experimental Pathology, Pick Congress Hotel, Chicago, Apr. 11-15. Dr. J. F. A. McManus, Univ. of Alabama Med. Center, Birmingham, Ala., Executive Secretary.

American Society of Facial Plastic Surgery, Hotel Elysee, New York City, Apr. 6. Dr. Samuel M. Bloom, 123 E. 83d St., New York 28, Secretary.

American Society of Internal Medicine, Sheraton-Palace Hotel, San Francisco, Apr. 1-3. Mr. Robert L. Richards, 350 Post St., San Francisco 8, Executive Director.

American Society for Pharmacology and Experimental Therapeutics, Inc., Chicago, Apr. Dr. Karl H. Beyer Jr., Merck Sharp and Dohme Research Labs., West Point, Pa., Secretary.

American Society for the Study of Sterility, Sheraton-Gibson Hotel, Cincinnati, Apr. 1-3. Dr. Herbert H. Thomas, 920 S. 19th St., Birmingham 5, Ala., Executive Secretary.

American Surgical Association, The Greenbrier, White Sulphur Springs, W. Va., Apr. 3-6. Dr. W. A. Altemeier, Cincinnati General Hospital, Cincinnati 29, Secretary.

CURIOSITY, CULTURE, AND CURRICULA

William Dock, M.D., Brooklyn, New York

WHEN Chaucer described the doctor who rode with his pilgrims to Canterbury, he credited the "parfit pratisour" with knowing the works on medicine of many Greek, Latin, Arabic, French, and British authors. But he added drily: "His studie was but litel on the bible." In the ensuing 600 years there has been much comment about the physician's lack of interest in "the noblest monument of English prose." The esthetic as well as the ethical attitudes of our culture are based on the Bible, and it may well cause concern that a profession with high social status and authority over the bodies and minds of men should have impressed so many acute observers as being unconcerned about culture and religion.

Location of Medical Schools

In the past year two medical schools of great repute, Johns Hopkins and Leland Stanford Jr., have implemented long-considered plans to do something about this situation. As was stated at the dedication of the new medical center in Palo Alto, the decision to move from San Francisco and from the long-established center with facilities for research and one of the best library buildings of any medical school in the world was based on the "desire to encourage concurrent study of the arts, literature, history, religion, politics—in other words, the humanities and social sciences—during all the years the medical student is preparing to accept the responsibilities of being a doctor."

In choosing locations for new medical schools the relative advantages of large cities as against university communities must be considered. A medical student on a university campus has perhaps stronger inducements for formal study of cultural subjects, but opportunities for self-education in humanities, social studies, and natural sciences also abound in large cities. Curricular revisions, if they are to encourage advanced education in sciences or humanities, must provide for courses to be taken without regard to credit either for advanced degrees or for the medical degree. To stifle curiosity and discourage spontaneity is to impose on a faculty the burden of bored pupils. To reduce the required core of medical instruction to a minimum and to provide real freedom of choice in the studies of the physician is perhaps the most urgent need in medical education today.

It is obvious that university trustees and administrators, always under great financial pressure to meet current expenses, do not give up a going concern which it would cost millions of dollars to replace unless they feel some great need for change.

From the Department of Medicine, State University of New York, Downstate Medical Center.

In this case, concern over the cultural education of medical students was decisive. Many fine medical schools are miles from the university campus—Johns Hopkins, Harvard, University of California at San Francisco, University of Southern California, Tulane, and Washington University. A few are scores or hundreds of miles from the university—Cornell, Illinois, and Kansas. The issue raised by Johns Hopkins and Stanford, and going back at least to Chaucer's day, is clearly one of great importance, especially if it can be met only by moving the medical schools.

Because of the increasing population and increasing per capita demand for medical care, it is obvious that facilities for medical education in the United States will have to be greatly increased. Costs will be the main restraining factor, with lack of personnel next. It therefore is necessary to seek answers to the questions of where it is best to have the medical student receive his education and of how personnel can best be used to provide education for all professions.

The reason that medical schools are not on university campuses is obvious. Only state-supported schools can afford to operate hospitals, and the largest concentrations of patients exist in large cities, where funds, municipal or charitable, support the great hospitals used for teaching. At Harvard and at Washington University in St. Louis the medical schools were built to be near indigent patients and busy clinicians rather than the university. Prosperous donors, who want the best medical care, usually live or make their fortunes in large cities and support the great private teaching hospitals. But even in some state schools, such as the University of California at San Francisco, consideration of the able clinicians, who are concentrated in the city and not the university towns, may establish the advisability of having medical students away from the campus and in a lively metropolis noted for its cultural activity.

In the past, American university towns provided little culture; one had to go to cities for music, museums of art, theaters, and examples of great architecture. Today, with tapes and records, one can study great music in submarines under one pole or snow-bound camps on the other, as well as in remote ranches or villages. Television and the cinema bring great acting, as well as trash, to most college towns.

Literature could always be studied away from libraries, and the rail-splitter in his cabin in Illinois learned more about English prose and humanity from the Bible and Blackstone than his fellow speaker at Gettysburg from the best schools and colleges of New England. Today there is little advantage in having a medical school in a city in order to provide the students with a cultural environment. With the increase in the number of paying patients and their participation in medical education, and the growth of population and number of able clinicians in university towns, the need for placing medical schools near city hospitals or heavily endowed charity hospitals, with large private patient facilities to attract good clinicians, is gradually becoming less urgent. Thus the reason for building a medical school far from the college town is rapidly vanishing at a time when the opportunity for self-education in the arts and humanities, anywhere on earth, is greatly expanded.

Another reason for having the medical school away from urban congestion has become obvious in the last two decades. More and more prosperous young married people live in suburbs, and the husbands, including a high proportion of full-time medical school faculty members in metropolitan areas, waste two or more hours of each day commuting. Putting the medical school on a suburban campus or in a college town ends this. The temptation to work a five-day week, to which not a few faculty members have succumbed, is removed. When the university is in a great city, as are Columbia, Pennsylvania, and Chicago, the best hope is for developing a pleasant "college village," with adequate open space and grammar schools, near the campus. Perhaps, in future evaluation of colleges, the percentage of full-time faculty members living within two miles of the school will be considered. Certainly the move at Stanford has enabled faculty members to move closer to the college of medicine.

If we agree with Dobzhansky that man is unique in having a "genetic basis for the capability for extragenic transmission of a body of learned tradition called culture," we will agree that failure to receive an optimal amount of culture is a personal misfortune, comparable to deafness or blindness. It is also a misfortune for the community, for failure to transmit to a maximal number of citizens the largest and best parts of our tradition is the surest way to worsen human condition and return to primitive ways. The transmission of culture to physicians and to all other citizens is therefore the most important and truly human function of society, and the nation should prepare to meet whatever changes are needed to aid this process.

It would, of course, be most interesting to give spot examinations on the cultural level of recent medical graduates of Cornell, Harvard, Johns Hopkins, and California at San Francisco, which are not near the university campus, and to compare the results with those of similar tests for graduates of the universities of Minnesota, Michigan, Chicago, and California at Los Angeles, who have been in schools on the campus. My impression that there is no difference either between the most cultured or between the least cultured graduates of these two groups of schools may prove to be erroneous, and a real advantage of one kind of school over another might be established. It should be emphasized that culture is largely transmitted by books, and the knowledge of literature, history, and biography, rather than appreciation of music, fine arts, or the stage must be regarded as the basis of culture. Yet the examination of the young physician's culture should cover a wide spectrum. In a few years, comparisons can be made between the future graduates of Stanford and Johns Hopkins and the graduates of those schools which continue to offer only medical courses to students admitted to medical school. The end of the year of internship would be the best time for such tests, and, for good measure, the same tests should be given to a cross-section of the preclinical and the part-time and full-time clinical teachers as well as to administrators and trustees of the medical college. The tests would be taken anonymously and results reported only according to categories and age groups. The cost of examining the cultural status of physicians would be a small fraction of the amount that foundations have contributed for study of the medical curriculum and minute compared to the cost of moving one school from an urban site to a suburban campus in order to raise the students to a higher level of culture.

Interest in Culture

Those who draw plans for new medical schools or consider making changes in the existing ones will give careful consideration to the experiments at Stanford and Johns Hopkins. In any attempt to raise the cultural level of physicians in the United States, one must contend with the lack of respect, if not contempt, with which the great literary and artistic traditions of humanity are treated in North America. In New York City, musical comedies of little merit draw crowds for years, while a moving production of Tolstoi's "Power of Darkness" will draw an audience of about 200 on good nights for a few weeks. Cultured physicians, like cultured governors, are considered a bit odd rather than exemplary. In plans for a more intense cultural education for physicians this opinion must be taken into account, for many fledgling physicians share the national attitude and are repelled rather than attracted by obligatory courses in humanities or social sciences.

In the English language we have many forceful statements of the problem which disturbs all teachers: "You can lead a horse to water but you can't make him drink." Francis Bacon observed that "the best part of a man's education is that which he gets for himself." Gibbon, ruminating on the folly and lack of cultural interests of so many well-educated Roman emperors, concluded that "the power of education seldom has any efficacy save in those happy dispositions where it is almost unnecessary." The new testament (Luke 16:19-31) gives an astounding picture to illustrate this widely recognized problem. The young teacher told his disciples how father Abraham in heaven had replied to Lazarus' plea from hell that the transfigured beggar be allowed to return to earth and warn his relatives of the truth about the hereafter. Said Abraham: "They have Moses and the prophets; if they hear them not, neither will they be persuaded if one rise from the dead." Christ knew that the death and resurrection of a Messiah would not influence men to adopt the golden rule or follow the Ten Commandments if they had ignored the teachings of their parents and the writings available to all men.

The general resistance to cultural influences, noted by keen observers for two millenniums, and the antagonism to culture peculiar to the United States may make some feel that it is hopeless to expect young persons to benefit from an opportunity to take additional college courses during the years they spend in schools of engineering, law, business, or medicine. These doubters will feel that those persons whose curiosity about the humanities and social sciences has not been awakened by school, family, friends, or newspaper and magazine articles, by the time they are 18 years of age, are not going to have any real interest in such topics while seeking to get ahead in professional courses. The doubters will recall that many highly cultured physicians have had no college courses at all. Sir James MacKenzie, the widely read and profoundly humane physician who revolutionized our view of heart disease, spent 90 hours a week as a druggist's apprentice during the time he was 15 to 21 years of age; he entered Edinburgh medical school with little more than grammar school education. Laennec, the greatest clinician of the 18th and 19th centuries, conducted ward rounds in Latin but had no cultural courses after the age of 17 years. He had taken courses in natural science, Latin, and Greek for two years after he started his work in the hospital as a medical student, before his 15th birthday. He was also a passionate flutist and lover of music.

On the other hand, many business and professional men with A.B. degrees from fine colleges exhibit a complete lack of cultural interest in later life, an atrophy of the mind not unlike the softening of the body of those athletes who become completely sedentary after college. Obviously all these facts were known to the authorities at Stanford and Johns Hopkins, but they must have concluded that none of the facts negated the thesis that "a fine education enhances a native talent" or justified a hopeless attitude toward improvements in teaching. Christ, Francis Bacon, and Gibbon devoted themselves to instructing those who would learn, and it is this group for whom the curricular changes were instituted.

The current system of selecting students for medical school rarely places much value on the curiosity and zeal for self-education which, along with having cultured parents and spending one's childhood and adolescence in a cultured neighborhood, form the real basis for an interest in the great traditions and in the cultural growth of the race. Overcrowded schedules and busy professional lives make it certain that only those students who have curiosity and whose interests have been directed into cultural fields before they go to college will show any real cultural improvement during the late teens and 20's. After they have reached the age of 30 years, especially if they happen to have cultured wives and friends, business or professional men may show a genuine devotion to learning which will continue through life and predispose their children to seek culture. But this phenomenon is often most striking in those who are curious but had little formal drill in the humanities before they entered a professional school. Herbert Hoover is an outstanding example of a person with this broadening of interests. He has always read widely and wisely, and when he was in his 40's he helped translate and publish Vitruvius' textbook on mines and mining in the Middle Ages. Those whose social status and satisfaction in their education have been provided by a college degree are more apt, when they are middle-aged, to take up horticulture, gourmet cooking, ornithology, or some other hobby to which they were not immunized by formal education taken for a degree rather than to satisfy curiosity.

Curriculum and Environment

Between the ages of 16 and 35 years, people entering professional fields have little time to explore new aspects of culture. The opposite sex and establishment in a profession make all other aspects of life seem remote, but acquisition of culture does continue among those "happily disposed" by nature and nurture. If it is made attractive because they admire cultured teachers and have easy access to books, theaters, concerts, and art museums, they make greater gains, and those not so well disposed are less likely to lose interest in culture if they are in a good environment during this period.

One way in which any medical school can further cultural growth was pointed out to me by Sir George Pickering, Regius Professor of Medicine at Oxford. This is to provide a good classical library in the medical school containing the great books and plays, novels, poetry, works on music and the arts, and books on philosophy, anthropology, sociology, and the history of all the sciences, as well as general history and biography. The use of this library would provide an index of the zeal for culture of the faculty, the interns, residents, and students; it would permit concurrent study of a field somewhat wider than the humanities and social sciences. The cost of such a wing in the medical library would be negligible in view of its contribution to cultural growth during the formative years of the physician.

It is unlikely that required courses in these fields will attract better students to enter medicine, and they may not significantly raise the cultural level of students whose sole interest is in medicine. Even in schools on university campuses it seems unlikely that elective courses in these fields will be selected, even by those students of medicine who already have a lively curiosity about the humanities and social sciences, in preference to advanced courses in mathematics, physics, chemistry, psychology, or biology. The difficult courses in these fields are usually avoided by premedical students, since low grades in them might jeopardize admission to medical school; yet the need for these disciplines becomes evident to any student of biochemistry, physiology, or psychiatry. Forty years ago I was glad to go to summer school and take physical chemistry from Professor Harkins of Chicago after my freshman year in medicine, but this course was not needed for credit and I was not concerned about the grade because it could not affect my class standing. (A reformed versifier, I also took a course on Tennyson and Browning that summer.)

The value of any curricular revision made to encourage advanced education in science or the humanities will be greatest if such courses can be taken with no regard to credit, either for advanced degrees or for the medical degree. Then the teachers will have to deal only with students interested in the courses, and course selection will not be influenced by the reputed ease of getting good grades. Everyone is aware of the demoralization of American students by the required-hours system and the availability of "pipe" courses. Equally glaring is the corruption of the research field resulting from paying undergraduates for doing summer research and giving credit for research fellowships in setting standards for specialty certification. When Opie and MacCallum did undergraduate research on malaria, or Grant and Mudd on the tetany during hyperpnea, or Best on glycosuria, no academic credit was given, and the department head did not wonder whether they had come to satisfy curiosity or to get cash or credit. Today the goal of students is not so clear, and opportunity for research by students with genuine curiosity is lessened because of the time and facilities wasted on credit-seekers.

There is strong evidence that an increase of 20 to 50% in the number of physicians graduated each year is needed to take care of our growing population, and the increase should be even greater if we are to provide schooling for foreign students and physicians planning to work and teach in the less favored younger nations. Yet every dean and admissions committee member feels that there are not enough qualified people applying for medical training today. To remedy this situation more superior students should be admitted to medical school after two years of college, and the required number of hours in every department should be cut to the minimum accepted by state or national board examiners. This would give intelligent students more time to devote to those phases of medical, humanistic, or scientific study which really interest them. Teachers in the required courses can do much to make clear the value of making up defects in basic education or broadening one's interest in culture and the living world. If time is made available without increasing the number of years spent in medical school, many students would take advantage of opportunities to study in libraries, night schools, or summer schools and, in medical schools which are part of the university community, in the college or graduate schools.

Sound and inspiring teaching in the preclinical sciences leaves no doubt in a student's mind that mathematics, organic chemistry, and physical chemistry would be invaluable training for which the curriculum made no provision whatever. Similarly, the teaching of Osler, Cushing, Herrick, and other cultured physicians has awakened a desire for better acquaintance with literature and history in many medical students and interns, and probably the teaching of outstanding men in psychiatry and environmental medicine has created in some students a desire to do advanced study of psychology and the social sciences. Only the most gifted and eager student is likely to profit by advanced study in all three fields simultaneously, but opportunities and facilities for such study in one or more fields seem desirable for medical students. When the medical school is on the campus, perhaps instructors and professors will also take courses in mathematics, science, and humanities and set an example to their classes.

The curriculum suggested would allow the average student to take as many hours in medical school courses as are necessary to prepare him for the type of practice he plans to enter, while giving time for additional medical studies for slow learners and for nonmedical studies by those with such interests. This program, and correlation of courses in the medical school with courses in the college or postgraduate schools in other fields, can be put into effect now by the many schools already on university campuses. Elsewhere, various arrangements could be made, depending on the community in which the school is situated and the distance from a large or at least well-rounded library, to encourage students to study and to discuss with a faculty member cultural or scientific fields in which they have a mutual interest.

Thus, on the sound pedagogical principle that leading horses to water is futile when they are not thirsty, one may provide as much good water as possible, knowing that thirsty horses will seek it out. In this way the facilities for additional education and time for additional study in the fields most profitable to each student can be offered to every medical student. Some may prefer to improve their golf or skill at cards if the faculty can interest them only in the courses required to meet licensure qualification. It is better for students to use their spare time playing games than it is to impose on instructors and professors the burden of bored pupils. Zealots for culture may need to be reminded that Hopkins' great dean, Professor William Welch, devoted many hours each week to whist during his academic years, preferred baseball to Brahms, and burlesque to Chekov.

Providing free time and then insisting that it be filled with required "electives" is not going to develop power of discrimination, nor will such a program produce dedicated students or cultured physicians. On the other hand, making available a wide range of self-educational programs and opportunities for advanced study and research and offering no academic reward for time well-spent or penalty for time wasted serves to develop judgment and responsibility in young people and makes it easy for an intelligent faculty to distinguish the sheep from the goats in their flock. It is absurd to say that it is unwise to entrust the disposition of free time to young men and women when we know that in two or three years they will be responsible for decisions on which life or livelihood for many patients will depend. The sense of responsibility for the lives of others can best be developed by having responsibility for choosing what to do with one's own life, or that small fraction of the day not occupied by essential duties. "I cannot praise a fugitive and cloistered virtue, unexercised and unbreathed, that never sallies forth to look upon her adversary, but slinks out of the race where that immortal garland is to be run for, not without dust and heat." Neither Milton's imagery nor Harvey's profound biological insight would have reached heights which astonished the world if their early years had been occupied by a rigid curriculum and required hours in "elective" courses rather than in the freedom of study granted even to youths 17 years of age at Cambridge.

Summary

To reduce the required core of medical instruction to a minimum and to provide real freedom of choice in the studies of the physician is perhaps the most urgent need in medical education today. In the medical schools already on the university campus it is possible to offer a wide choice of studies. When this is not the case, it may be worthwhile for medical school faculty members to assist the cultural and scientific growth of students, an experience entirely missing when the college automatically provides instruction in all these fields. Variety in types of medical schools, as well as in the educational experience of medical students, is far more important than a uniform "ideal" curriculum or a uniform "ideal" medical educational center. Few medical schools can scrap the existing plant and start anew, but all can increase the use of the facilities they have; provide better library facilities for self-education in humanities, social, and natural sciences; and carry out experiments in improving the selection, admission, and education of their students. In planning the necessary new schools, advantages of urban location or campus sites will have to be considered from many angles, since both have many valuable features.

450 Clarkson Ave. (3).

EIGHTH NATIONAL INTERN MATCHING PROGRAM

Ward Darley, M.D., Fred Meier
and
Alice Skarzynski, Evanston, Ill.

In 1959 about 96% of the 6,850 students graduating from United States medical schools and 98.1% of 834 hospitals having approved internship programs participated in the National Intern Matching Program. The hospitals accepted 6,478 interns in this manner, and 251 students failed to secure internships through the services of the program. In 89% of the matches made, both the hospital and the students were able to obtain their first or second respective choices.

This will be the eighth annual report of the National Intern Matching Program (NIMP). Some, but not all, of the basic data that have characterized previous reports are being continued. Some data that have not been published for several years are being brought up to date and other data are being included for the first time. The data that may be missed are those which have shown the distribution of matched internships according to nature of hospital affiliation, amount of stipend, and number of interns sought and matched. A review of last year's report, tables 5 through 16,[1] will reveal that these data were handled in such a way as to show the changes that had occurred between 1953 and 1958. It is now planned to repeat the presentation of these tables only as further changes may justify—perhaps once every two or three years.

In table 1 are reviewed the numbers and percentages of United States graduates and approved hospitals and internship programs participating in NIMP since its first report in 1952. While the initial participations were all over 90%, it was not until 1955 that the present high levels were reached. The percentage of participation of United States graduates is lower than that for hospitals and programs, for a variety of reasons. A few students deliberately stay out of the program, some to take an internship in a hospital awaiting approval and one, therefore, that is not yet eligible for participation. A small number do not take an internship or defer internship because they go directly into research or graduate study. The principal reason for nonparticipation is a decision to intern in a nonparticipating hospital. This situation applies particularly to Tennessee; the University of Tennessee graduates about three-quarters of its seniors at times of the year that do not fit into the NIMP timetable. Thus those hospitals, most of them in Tennessee, that wish to accept students who graduate at odd times, find it necessary not to participate.

Table 2 continues the tabulation of general data that has characterized previous reports. As predicted in last year's report,[1] because of the decision of NIMP to require screening by the Educational Council for Foreign Medical Graduates, there was a sharp drop in foreign graduate participants (376 to 4). Because of this, a considerable drop in the number of graduates going unmatched also was predicted. Table 2 shows that this proved to be the case. Beginning with the 1960-1961 program, the number of foreign participants will again increase and, as a consequence, because of ECFMG screening, it is predicted that the percentage of foreign graduates matched will show a substantial increase over previous years.

Tables 3 and 4 show the type, number, and percentage of internships offered and filled through NIMP for 1952, 1954, and 1959. The number of rotating general internships offered has increased, but the number and percentage matched has dropped. The number of straight internships offered and the number matched have increased and as a consequence the percentage matched has shown a sharp increase—59 to 75%. The category "other internships" includes miscellaneous types of mixed internships with varying kinds of emphasis; consequently, they cannot be classified as either rotating or straight and must be dealt with separately. These kinds of programs and internships are falling off in number but have shown a slight gain as far as their percentage of matches is concerned.

The recent drop in the percentage matched for all internships is a reflection of the fact that the number of internships being offered is growing proportionately faster than the number of available graduates. Of the straight internships, except for those in obstetrics and gynecology, there has been a slight increase in number and also an increase in the percentage matched. For each of the three years noted in table 3, the total number of straight internships offered as a proportion of all internships offered has retained approximately the same relative position—10.5, 9.5, and 11.4%, respectively; but of the total number of all internships matched, the share falling to the straight internship has shown a modest increase—11.7, 12.0 and 16.3% respectively. (Both of these calculations are made from but not shown in table 3.)

Tables 5, 6, and 7 show the continued leveling off of the number of internship applications per student, the percentage of students matched by order of choice, and the hospitals' ranking of students with whom they were matched. In past reports it has been assumed that the downward trend (1952 to 1958 particularly) in the percentage of students being matched for first choice was an indication that students were adding, as first choice, institutions in which they felt their chances for acceptance were open to question but in which they would like to intern if they possibly could. Students can feel free to make such "tries," because in such instances they are not hurting their chances for their second and third choice hospitals—hospitals which otherwise they would list in first and second places.

Table 8 reports a more definite analysis of what happens as between students who make few choices and those who make many. Students who make fewer applications tend to be matched with hospitals that fall the shortest of filling their quotas. As the number of applications increase, the chance of being matched with a hospital that fills or comes close to filling its quota is increased.

While last year's report [1] dealt in detail with the background, history, mechanics, and timetable of the NIMP, it did not indicate the manner in which compliance with the program's agreements was administered. After eight years' experience, a discussion of this aspect of the matching program is indicated.

Table 1.—*Number and Percentage Participation of United States Graduates and Approved Hospitals and Programs, 1952-1959*

	1952	1953	1954	1955	1956	1957	1958	1959
Total United States graduates participating	5,617	5,947	6,258	6,533	6,430	6,498	6,576	6,562
Total United States graduates	6,153	6,418	6,672	6,870	6,719	6,689	6,862	6,850
Percentages of U. S. graduates participating in NIMP	91.3	92.7	93.8	95.1	95.7	97.1	95.8	95.8
Hospitals participating in NIMP	795	808	820	814	821	822	819	818
Total approved hospitals	826	833	836	826	834	833	835	834
Percentage of hospitals participating in NIMP	96.2	97	98.1	98.5	98.4	98.7	98.1	98.1
Total intern programs offered	1,068	1,102	1,032	1,056	1,063	1,052	1,062	1,069
Total approved intern programs	1,102	1,130	1,048	1,068	1,076	1,063	1,078	1,085
Percentage of programs participating in NIMP	96.9	97.5	98.5	98.9	98.8	99.0	98.5	98.5

In the first place, it must be remembered that, for both hospitals and graduates, the decision to join the program is voluntary. A hospital or student, once this decision has been made, applies for, signs, and returns the appropriate agreement. The board of directors of NIMP, which consists of three representatives each from the American Medical Association and the Association of American Medical Colleges, two from the American Hospital Association, one each from the Catholic and Protestant Hospital Associations, one from the Student American Medical Association, and another student representing the national medical student body at large, establishes the terms of these agreements, must authorize any changes therein, must decide questions relative to their interpretation, and, finally, must approve any action taken in connection with their infraction. The hospital and student agreements for the 1960-1961 program follow.

Table 2.—*General Results, 1952-1959*

Year	Hospitals Participating	Intern Programs Offered	Total Positions Offered	Total Positions Filled No.	Total Positions Filled %	Number Unfilled Positions	Students Participating	Students Unmatched
1952	795	1,068	10,414	5,564	53	4,850	5,681	117
1953	808	1,102	10,971	5,744	52	5,227	6,033	289
1954	820	1,032	10,729	6,051	56	4,678	6,412	361
1955	814	1,056	11,075	6,379	58	4,696	6,713	234

Hospital Agreement

On behalf of the hospital named above, I agree to abide by the regulations of the National Intern Matching Program for appointment of interns for first-year internships for 1960-1961 (starting service from April 1 through Dec. 31, 1960).

In particular, it is understood that this hospital is agreeing to (1) offer internship appointment to all applicants matched with this hospital by the matching program, the matched students being the highest ranked students on this hospital's confidential ranking form who wish to intern here more than at any other hospital available to them; (2) restrict internship appointment for United States and Canadian applicants to participants designated for this hospital through the matching program, until after notification of the selections made through the matching program; (3) make or require no commitments or contracts with United States or Canadian applicants prior to the notification of the selections made through the matching program; (4) abide by the official schedule, including accepting no applications from participants in the matching plan after Jan. 25, 1960, and rating applicants and returning rating form by Jan. 30, 1960, offering formal appointment promptly to persons matched by the plan with this hospital no later than March 31, 1960; (5) not accept an intern who was matched elsewhere and subsequently not released (this condition was made a part of the agreement beginning with the eighth matching program); and (6) pay a service fee of $4 for each intern matched through the plan.

We understand further that, although we may freely discuss any matter we choose with the student, no participating hospital has the right, under the plan, to demand or to require that the student state how he will rank this hospital on his confidential rating blank. We also understand that the student has no right to request or to demand that this hospital inform how it plans to rate him.

Furthermore, any statement or other expression concerning how this hospital intends to rank an applicant or how that applicant intends to rank this hospital, which may be made during the free discussion between the hospital and the student, is subject to change based on further considerations. We understand that we, as well as the student, have the right to change our minds at any time prior to the submission of the official confidential rating blanks.

TABLE 3.—*Types and Number of Internships Offered and Filled Through NIMP Since 1952*

	Rotating General Internships			Straight Internships			Other Internships			All Internships		
	1952	1954	1959	1952	1954	1959	1952	1954	1959	1952	1954	1959
Program no.	1	3	8	1	3	8	1	3	8	1	3	8
Number offered	8,596	9,343	10,453	1,098	1,025	1,398	720	361	399	10,414	10,729	12,250
Number matched	4,479	5,092	5,141	656	728	1,060	429	231	277	5,564	6,051	6,478
Percentage matched	52.1	54.5	49.2	59.7	71	75.8	59.6	64	69.4	53.4	56.4	52.9

The confidential rating blank submitted by this hospital and confirmed, is to be the sole determinant of the order of our preference among our applicants.

Student Agreement

I agree to participate in and abide by the results of the matching plan for internship appointment. In particular, I understand that I am agreeing (1) to apply for internship appointment only to hospitals and the federal services registered in the matching plan until after the matching plan results are announced. I understand that an official directory listing the cooperating hospitals and federal services will be available in October, 1959; (2) to accept appointment to the hospital or federal service with which I am officially matched, that hospital being the highest one on my preference list having a place available for me. I understand that I cannot avoid accepting an internship to which I have been matched without a written release from the hospital concerned—also that another hospital that is a member of NIMP cannot accept me as an intern unless I have this release (this sentence was made a part of the agreement beginning with the eighth matching program); (3) to abide by the official schedule, including ranking the internships for which I have applied and returning my confidential ranking form before Feb. 1, 1960; and (4) to send herewith a nonrefundable fee of $2 to help cover the costs of participation in the matching plan.

TABLE 4.—*Type and Number of Straight Internships Offered and Filled Through NIMP Since 1952*

	Medicine			Surgery			Pediatrics			Obstetrics-Gynecology			Pathology		
	1952	1954	1959	1952	1954	1959	1952	1954	1959	1952	1954	1959	1952	1954	1959
Program no.	1	3	8	1	3	8	1	3	8	1	3	8	1	3	8
Number offered	503	546	674	364	358	425	121	113	209	51	8	27	59	...	63
Number matched	359	434	586	202	231	310	69	62	121	11	1	5	15	...	38
Percentage matched	71.4	79.5	86.9	55.5	64.5	72.9	57	54.9	57.9	21.6	12.5	18.5	25.4	...	60.3

It is my understanding that I am free, under the matching plan, to make personal contacts with any participating hospital in which I am interested and to apply to as many of these hospitals as I wish and to rank them according to my judgment.

I understand further that although I may freely discuss any matter I choose with the hospital, no participating hospital has the right, under the matching plan, to demand or to require that I state how I shall rank that hospital on my confidential rating blank. I understand also that I have no right to request or to demand that that hospital inform me how it plans to rate me.

Furthermore, any statement or other expression concerning how I intend to rank a hospital or how that hospital intends to rank me, which may be made during the free discussion between the hospital and myself, is subject to change based on further considerations. I understand that both the hospital and I have the right to change our minds at any time prior to the submission of the official confidential rating blanks.

My confirmed confidential rating blank, giving my order of preference, is to be the sole determinant of the order of my preference among the internships for which I have applied.

I understand that resignation from the matching program can be made only with the approval of my dean, and that no resignations can be accepted after Nov. 14, 1959.

I agree to conduct myself in conformity with the high ethical standards expected of members of the medical profession.

General Comments

Withdrawal from the program is optional for both hospitals and students, if the timing and manner of withdrawal comply with the timetable and provisions of the signed agreements. In the case of student withdrawal, the concurrence of the respective dean is required. Within two weeks after the matching results have been announced, students and hospitals should recognize their matchings by formal contract. The NIMP agreements with both student and hospital can be considered satisfied as soon as the intern begins service. These procedures tie in with the following statement, which appears in "Essentials of an Approved Internship" of the Council on Medical Education and Hospitals of the American Medical Association.

TABLE 5.—*Applications per Student*

Year	Students, No.	Applications, No.	Applications per Student, No.
1952	5,681	21,728	3.8
1953	6,033	19,416	3.2
1954	6,412	21,579	3.4
1955	6,713	25,617	3.8
1956	6,821	29,474	4.3
1957	6,923	30,434	4.4
1958	7,131*	32,090	4.5†
1959	6,729	29,416	4.4

* Incorrectly carried in Seventh Annual Report as 7,031.
† Incorrectly carried in Seventh Annual Report as 4.6.

> *Hospital-Intern Agreement.*—A formal agreement in which mutual obligations are defined should be entered into between the hospital and the applicant at the time of his appointment. This agreement must be honorably fulfilled by both parties and should be terminated only by mutual consent. A breach of the agreement by either a hospital or an intern is not condoned by the Council. Whenever complaint of such a breach is made, it is the policy of the Council to ask each of the parties involved to submit an explanatory statement. Such statements become a part of the physician's and the hospital's record and are made available on request to authorized agencies.[2]

The few questions of irregularity that do occur, unless resolved early in their development, can become complicated and difficult. Therefore, once a hospital, student, or dean is aware of a question that can lead to possible infraction, experience has shown that the quicker such is made known to the NIMP office, the better. Most such situations are the result of failure to read the NIMP agreements carefully, lack of understanding, or inadequate communication. The NIMP office, communicating with the appropriate deans, students, and hospitals, has usually been able to assist with the resolution of these questions to the satisfaction of all concerned. Of course, reports of irregularity that are not supported by a statement of the pertinent facts and a willingness to be quoted do not lend themselves to investigation.

TABLE 6.—*Percentage of Students Matched by Order of Choice*

	Choice			
Year	First, %	Second, %	Third, %	Fourth or Lower, %
1952	84	10	3	3
1953	85	10	3	2
1954	82	11	4	3
1955	76	14	5	5
1956	74	15	6	5
1957	76	13	6	5
1958	74	14	6	6
1959	77	12	5	6

Any cases that go to the point of probable infraction are reviewed by the executive committee of the board of directors and later by the board itself. In case of established infraction on the part of a hospital, the board can determine that copies of the pertinent correspondence be filed with the Council on Medical Education and Hospitals of the A. M. A. If the infraction involves a student, the board can determine that copies of the pertinent correspondence be filed with the Biographical Records Section of the A. M. A. The most common questions of infraction center around the acceptance of a student, without release, by a hospital other than the one to which he or she has been matched. Such instances involve the accepting hospitals as well as the students. As a consequence, when the correspondence pertinent to a proved case of such infraction is filed with the A. M. A., the names of both the hospital and the student will appear.

TABLE 7.—*Hospitals' Ranking of Students with Whom They Were Matched*

Year	Percentage Matched from Rank Group 1*	Percentage Matched from Rank Group 2	Percentage Matched from Rank Group 3	Percentage of Others	Total, %
1956	61	24	11	4	100
1957	71	19	7	3	100
1958	67	22	8	3	100
1959	69	21	8	2	100

* If hospital quota is 10, first 10 men on list form rank group 1 and numbers 11-20 rank group 2, and the ranking continues by groups of 10.

Fortunately, instances of the need for any such action have been rare. In fact, considering the thousands of persons who are involved in the entire NIMP enterprise—hospital administrators and staffs, students, deans, and faculty advisors—the incidence of any kind of difficulty is small indeed. Cooperation on all sides has been the rule. This shows that the principal force that is responsible for the smooth operation of NIMP is the spirit of fair play that originally made the program possible and that has since prevailed.

TABLE 8.—*Comparison of Number of Applications made with Percentage of Positions Filled in Hospitals Where Applicants Were Matched*

Applications Made, No.	1	2	3	4	5	6	7	8	9 and More
Graduates Making Corresponding Number of Applications, No.	885	875	1,219	1,075	766	526	301	245	584
Intern Positions Filled Where Applicants Were Matched, %*	73	73	72	75	77	79	82	83	84

* The percentages of intern positions filled in the hospitals involved were computed by dividing the total intern positions filled by the number of positions offered.

IMMUNIZATION IN VIRAL HEPATITIS

Joseph Stokes Jr., M.D., Philadelphia

It is paradoxical that zinc-precipitated gamma globulin administered in small doses apparently could protect the recipient against epidemic hepatitis while the same material may produce serum hepatitis. Cold-ethanol-fractionated gamma globulin does not produce serum hepatitis but protects almost all exposed susceptible persons against the more severe symptoms of epidemic hepatitis. The most likely explanation is that in the carrier state hepatitis viruses of more than one antigenic strain are present in the blood stream and that the recipient of the carrier's blood can be protected by gamma globulin in accordance with how closely the transfused virus strain is antigenically related to the strain or strains responsible for epidemic hepatitis. The so-called passive-active immunization afforded by gamma globulin in epidemic hepatitis seems promising, and a method of testing it in closed institutions is proposed.

In the latter part of 1944, during World War II, gamma globulin of the American National Red Cross pools of plasma, fractionated by the cold-ethanol method of Cohn and Oncley, provided effective protection against infectious or epidemic hepatitis with jaundice, both in the armed services and in civilian outbreaks.[1] From the earliest studies on the epidemic disease it became increasingly clear that gamma globulin did not prevent infection with the virus but only reduced symptoms such as jaundice and that even in those exposed susceptible persons who had been injected with gamma globulin and later had no symptoms and negative results of liver function tests, infection probably still occurred. Thus developed the concept of passive-active immunization, as suggested by four widely separated outbreaks and injection of varying doses, ranging from 0.005 to 0.06 ml. per pound of body weight.[2]

Perplexingly, it remains a fact that such a blood product, obtained from the pooled blood plasma of adults, about 2 to 3% of whom are carriers of hepatitis virus in their blood, nevertheless has been universally protective against jaundice in literally hundreds of outbreaks of the epidemic disease. The figure of 2 to 3% of adult carriers is drawn from the fact that about 1% of persons transfused with single transfusions of whole blood in the United States and other nations contract hepatitis with jaundice. Since there will be at least one case, and possibly two, of hepatitis without jaundice for every case of hepatitis with jaundice which resulted from infective material, it is apparent that at least 2 to 3% of adult populations must be considered carriers. Unfortunately, no adequate tests for detection of this 2 to 3% of carriers are available.

To explain the puzzle of the protection provided by gamma globulin against parasites with which it has been intimately associated in the pools of plasma before ethanol fractionation, several hypotheses deserve consideration.

Possible Reasons

First, the most probable explanation is that the carrier state often occurs with hepatitis virus strains that are antigenically different from the epidemic strain or from strains of virus against which gamma globulin in small doses is so effective.

Second, in the carrier state the neutralizing antibody may be combined with the antigen and may be slowly dissociated from the latter during the long incubation period in the recipient, after the whole blood has been injected. Thus a latency of the antigen-antibody complex in the donor may be disturbed by the nonresistant recipient, who lacks the capacity to hold the virus in a latent or neutralized phase. If such separation of the virus-antibody complex occurs in the recipient, the virus may then infect, unless unusually large doses of gamma globulin are given immediately after transfusion and again one month later, when the dissociation has occurred and the long incubation period is well under way.[3] This possible explanation is apparently more attractive to those who feel that hepatitis viruses are all antigenically similar.

Third, a few cellular elements may be present in the pooled plasma that is used for fractionation, and the virus may be present in such cells, or fractions of cells, and thus may not be readily attacked by antibody, even though the pooled plasma may have a high titer of neutralizing antibodies to the virus. It is of interest, in this connection, that gamma globulin obtained through fractionation of pooled plasma by the zinc-precipitation method can contain hepatitis virus and in the studies of such fractionation was infective, usually with a long incubation period. Thus we have the paradox of a gamma globulin which can prevent the epidemic disease with jaundice but which has produced serum hepatitis with jaundice when injected parenterally, as

Read in the Symposium on Hepatic Diseases before the Joint Meeting of the Section on Experimental Medicine and Therapeutics, the Section on Gastroenterology and Proctology, the Section on General Practice, the Section on Internal Medicine, the Section on Pathology and Physiology, and the Section on Radiology at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 10, 1959.

demonstrated by Murray in volunteers. (This statement on prevention is not based on clinical trials but on the similar capacity of the zinc-precipitation and ethanol-fractionation methods to concentrate antibodies in the gamma globulin fraction.) The cold-ethanol method tends either to segregate the hepatitis virus in fraction 1, perhaps because of the nature of the molecule or of the antigen-antibody complex, or to destroy the virus in fraction 3, a destruction which does not occur with the zinc method. This may be because of the greater severity of handling in the cold-ethanol than in the zinc method. According to this explanation, latency in the carriers would be an intracellular phenomenon in the blood stream—perhaps in the red blood cells, the macrophages, or the leukocytes—and the antibodies of the plasma would not have access to the virus to inactivate it.

Fourth, the antigen-antibody complex which has been proposed as one hypothesis for the carrier state may actually be represented by a virus-inhibitor complex, in which the inhibitor is not a neutralizing antibody but protein molecules or mucoproteins to which the virus becomes attached and which prevent active infection of the host. Thus, the virus may be protected from inactivation in the presence of even large amounts of antibodies in the blood stream of the carrier. Again, these antibodies may be segregated by ethanol fractionation in the gamma globulin, while either the virus-inhibitor complex may be segregated in fraction 1, or the virus and the virus-inhibitor complex may be destroyed by the severe handling entailed in such fractionation. At the time of whole blood transfusion the virus-inhibitor complex in the blood of the carrier, who is the donor, may be slowly broken up in the recipient. The recipient then may either eliminate the virus or return it to a latent phase, which presumably could occur in tissue cells such as those of the liver, or in the blood—both intracellular and extracellular—or in both the blood and other tissues.

Of these four hypotheses the first, namely, that there are antigenically different strains of hepatitis virus, is the most attractive, because it is the simplest and generally corresponds to the experimental findings obtained in volunteers studied during World War II and immediately afterward. That such immunological problems are rarely simple was well illustrated by what appeared to be contradictory findings at that time in the study of serum hepatitis.

Results of Studies

Whereas small amounts of infective serum to which large amounts of gamma globulin were added in a neutralization test could still successfully infect volunteers,[4] field trials in a large hospital for evacuated casualties from all theaters of war nevertheless demonstrated that two 10-ml. doses of gamma globulin, injected one month apart, protected over two-thirds of the injected group against hepatitis with jaundice, as compared with the incidence in an adequate group of controls selected alternately.[3] In two other controlled field trials, in which only one 10-ml. dose of gamma globulin was used, the average incubation period was greatly lengthened, although the incidence of hepatitis with jaundice was not decreased.

Certainly these latter findings suggest that a slow dissociation of virus and neutralizing antibody or inhibitor is taking place in the transfused blood of the donor after it has entered the recipient, that the second dose of gamma globulin may be attacking the virus after its protective coat has been discarded during the earlier incubation phase, and that the first dose of gamma globulin may only add inhibitor or neutralizing antibody at a time when it may well increase the protective coat and lengthen the time before the recipient's immune mechanisms begin to act on the transfused and partially protected parasite. It was this rationale that originally suggested the use of two doses of gamma globulin at a one-month interval. On the other hand, there may be carriers of both serum hepatitis virus B and of epidemic or infectious hepatitis virus A, and the gamma globulin may give protection after transfusions, in accordance with the proportion of those donors who carry virus A or viruses of antigenic composition similar to A.

Recent additional evidence was obtained by Mirick,[5] with dosages and timings similar to those used in our studies. His studies on tuberculous patients who required whole blood transfusions suggested that injections of gamma globulin provided a protection similar to that obtained in our field studies on evacuated battle casualties, with the exception that Mirick's method included only two doses of gamma globulin, as in our original study, and not one single dose, as in our later studies. This partial protection given by two doses appears sufficiently important to make many persons who have seen the results of both studies at widely separated intervals hesitate to receive a transfusion of whole blood without such succeeding injections of at least two doses of gamma globulin. However, the relatively limited supplies of gamma globulin may deter widespread application of these suggestive findings.

It is difficult, however, to explain the findings in volunteers who were injected with infective serum (SH virus), followed by two doses of gamma globulin (10 ml. each) one month apart, in whom no apparent protection resulted.[4] It is conceivable that the virus with, at times, a long incubation period, even up to 194 days, may assume an inactive form, from which it is activated only in an environment suitable to its development, such as that of the recipient. Again, the reason for such lack of protection could be ascribed far more easily to antigenically different strains of virus.

Results of studies carried out on volunteers also suggest that certain strains of serum hepatitis virus (the virus which is always isolated from the blood, apparently never from the stool, and which usually has a long incubation period) do not produce permanent immunity, in that such previously infected volunteers may be reinfected parenterally and may show active symptoms at sufficiently separated intervals to avoid a suggestion of recidivation. On the contrary, the epidemic disease, on both experimental and epidemiologic grounds, tends to produce a more permanent immunity, particularly when it occurs in the younger age groups. However, the epidemic disease, in older persons, may continue as a subacute chronic infection, with a tendency to relapse and to fibrotic changes in the liver. Serum hepatitis, particularly in older persons, also shares the tendency to chronicity, severe relapse, and fibrosis of the liver.

Possible Applications

In view of the more permanent immunity which, before puberty, appears to occur after epidemic hepatitis and which receives some confirmation from the fact that doses of gamma globulin as small as 0.01 ml. per pound of body weight will protect most persons—at least against the overt disease with jaundice—the question naturally arises whether our far from complete knowledge of the disease would still permit some approach to active immunization, in addition to the passive immunization which has been so universally effective against epidemic hepatitis with jaundice.

Four studies[2] carried out in epidemics during and immediately after World War II, suggested that, in the presence of continued exposure to virus, passive immunization permitted inapparent infection and thus prepared the person injected with gamma globulin for active, and probably permanent, immunity. These studies have recently been confirmed by Ward and co-workers[6] in an institution on Long Island, Willowbrook, N. Y., where controlled studies carried out over several years have indicated the development of passive-active immunization in the resident children, who continued to be exposed to the disease in the institution after injection of gamma globulin (0.06 ml. per pound of body weight). In certain studies by Krugman and Ward,[7] filtrates of stool were used which were titrated by oral infection. The virus strain produced extremely mild disease and the incubation period was unusual in that it ordinarily ranged between 35 and 50 days, about midway between the mean incubation periods of recorded outbreaks of viral hepatitis A and of most outbreaks of viral hepatitis B.

This confirmation of the protection obtained against the more severe aspects of viral hepatitis by means of such a passive-active immunization highlights a suggestion made by our group some years ago that, in lieu of any method of growing the hepatitis viruses, passive-active immunization should be approached first in closed institutions, where epidemics so often occur. It is proposed that, in an institution in which the epidemic disease is pending, a single cottage be selected whose inmates, as far as can be determined, have not been fully exposed to epidemic hepatitis. A pool of plasma, obtained from a number of patients presenting mild cases of the disease during the acute stage and preserved with observance of adequate precautions, would serve as the orally administered infecting agent. Serologic tests for syphilis would be carried out on this pool. A suitable portion of the group in the cottage would be given orally the virus in the pooled plasma, and gamma globulin would be injected intramuscularly at about the same time, in a dose of 0.01 to 0.02 ml. per pound of body weight. Subsequent use of the virus of unknown titer in the pool and the amount of gamma globulin to be injected would depend on the results obtained in the original group. Sufficient experience has been accumulated in the four outbreaks already mentioned and in the recent studies at Willowbrook to warrant confidence in the safety and suitability of this method of immunization. Certainly, in groups of children who have not yet attained puberty even the unmodified virus may, in a mild outbreak, be used with little risk, and in the presence of antibodies, such as gamma globulin provides, there appears to be no danger whatever. On the contrary, this method of immunization could mean the saving of thousands of days of well-being lost to persons with both acute and chronic active hepatitis; the prevention of much chronic fibrosis, or cirrhosis, of the liver; and the prevention of many deaths in adults. Although the epidemiologic evidence in most instances favors permanent immunity to the epidemic disease after one sharp attack with jaundice, only experience with such a method of immunization would indicate how permanent it might be after anicteric infection.

Summary

Gamma globulin, produced by cold-ethanol fractionation from pooled human plasma, has been universally successful in protecting most exposed susceptible persons against the more severe symptoms, including jaundice, of epidemic viral hepatitis. The varying doses of this gamma globulin which are used by different researchers, i. e., from 0.01 to 0.06 ml. per pound of body weight, apparently have permitted anicteric infection with hepatitis virus in such exposed susceptible persons, frequently without symptoms. A number of such infections without symptoms, but not all, may be detectable by repeated transaminase or thymol turbidity tests.

Larger and repeated parenteral doses of such gamma globulin may have some protective value against serum hepatitis which results from parenterally administered blood products. Additional experience is required for final determination of its value for such protection. The paradox of possible protection obtained from zinc-precipitated gamma globulin administered in small doses against epidemic hepatitis, in contrast to the production of serum hepatitis by the same material, and the problem of protection against serum hepatitis are reviewed in several hypotheses, none of which is completely adequate in the absence of serologic tests for hepatitis viruses. Cold-ethanol-fractionated gamma globulin does not produce serum hepatitis. A possible approach to immunization against epidemic viral hepatitis in closed institutions, if successful, might be extended to large groups.

MULTIPLE INJECTIONS OF CRYSTALLINE INSULIN IN TREATMENT OF LABILE DIABETES

Henry L. Wildberger, M.D.
and
Henry T. Ricketts, M.D., Chicago

Fourteen patients with labile diabetes were treated with divided daily doses of crystalline insulin (CI). Prior to the exclusive use of CI the patients had been treated with protamine zinc insulin and crystalline insulin given separately or mixed, isophane (NPH) or lente insulin in single or divided doses, isophane (NPH) or lente plus crystalline insulin, or globin insulin alone, all of which provided unsatisfactory management. The CI was given in four daily injections, one before each meal and a small dose between midnight and 2:00 a. m. Despite the disadvantages of the nightly injections none of the patients insisted on resuming his previous insulin program. Divided daily doses of CI gave improved control of blood and urine sugar levels and diminished frequency and severity of insulin hypoglycemia.

Treatment of diabetes mellitus with divided daily injections of crystalline insulin is not a novel suggestion. For some years after the discovery of insulin this regimen was the only possible one. With the advent of insulins having a more prolonged action, therapy with crystalline insulin alone was largely supplanted. It has, however, found continued use among selected patients with labile diabetes.

Probably less than 5% of the diabetic population have a labile, brittle, or growth-onset type of diabetes. This group, while not large, presents serious problems in management. Treatment with any of the long-acting preparations of insulin commonly results in wide, unpredictable fluctuations of the blood sugar level so that excessive glycosuria and ketosis may alternate with hypoglycemia.

In 1950 Haunz[1] reported the use of multiple doses of unmodified insulin alone in six such cases. Control of the blood sugar level was clearly better than that obtained with other forms of insulin. We have

---

From the Department of Medicine, University of Chicago.

used this neglected method in selected patients since 1943 and now wish to report results in 14 patients.

Procedure

Fourteen patients (12 female and 2 male) were chosen primarily because of the difficulties presented in the management of their diabetes. Five patients had a history of ketosis or ketoacidotic coma, two had diabetic peripheral neuropathy, nine had diabetic retinopathy, and three had diabetic nephropathy with fatal termination. Inpatient records covering 14 to 21 days and outpatient records covering several months to 12 years were reviewed.

Hospitalized patients were given a diet that was constant with respect to amounts of carbohydrate, protein, and fat. Capillary blood specimens for glucose[2] were taken two to four times daily, and 24-hour samples of urine were collected for quantitative estimation of glucose.[3] Fractional urine specimens obtained before breakfast and three hours after each meal were tested qualitatively for glucose. Hypoglycemic episodes were recorded and described.

* Improvement in both blood and urine sugar levels is seen in two outpatients (cases 1 and 2) when treated with crystalline insulin only. All blood samples were taken 2 to 4 hrs. after lunch. Improvement in mean blood and urine sugar levels and an increase in the percentage of values falling within acceptable range are seen in four hospitalized patients (cases 3, 4, 5, and 6) treated first with long-acting insulin and subsequently with divided doses of crystalline insulin. Blood sugar values represent both fasting and postprandial determinations.

† PZI = Protamine zinc insulin; CI = crystalline insulin.

‡ Acceptable true glucose value, 60-150 mg.%.

§ Acceptable value, less than 20 Gm.%.

Outpatients collected 24-hour urine specimens for quantitative glucose analysis[4] one day prior to clinic visits and often, although not invariably, a specimen of venous blood for glucose analysis[5] was drawn two to four hours after the noon meal. Fractional urine tests performed by the patient at home and recorded by him were noted in his record, with a description of any hypoglycemic episodes. In general, physical examinations were done at least once a year and often more frequently.

All patients were first treated with one or, more commonly, several insulin preparations, including protamine zinc insulin and crystalline insulin given either separately or mixed, NPH or lente insulin in single or divided doses, NPH or lente plus crystalline insulin, and globin insulin alone. Two patients received tolbutamide in addition to a long-acting insulin but showed no significant improvement. Finally, treatment was started with divided doses of crystalline insulin given one-half hour before meals and a small dose between midnight and 2 a.m.

Means of both blood and urine glucose levels were determined for the periods during which the patient was given long-acting insulin and crystalline insulin alone. The percentage of blood-sugar values falling within an acceptable range of 60 to 150 mg. per 100 ml. (true glucose) and the percentage of 24-hour urine specimens containing less than 20 Gm. of glucose were calculated for all periods.

Report of Cases

Mean blood and urine sugar levels for two representative outpatients (cases 1 and 2) are presented in the table. The periods of observation were eight and six years respectively. A decline in hyperglycemia and glycosuria, with an increase in the percentage of results falling within the acceptable range, are seen during treatment with crystalline insulin. Case 1 is noteworthy and somewhat unusual in that the patient developed labile diabetes at 52 years of age. The table shows similar improvement in four hospitalized patients who were given crystalline insulin alone.

Figures 1 and 2 illustrate the daily blood and urine sugar values and corresponding insulin doses for patients in cases 3 and 6 respectively. Initially, marked fluctuation in blood and urine sugar levels was observed. A diminution in these crests and troughs, along with a general decline in glycosuria, occurred in patients treated with crystalline insulin alone.

Prior to treatment with crystalline insulin, hypoglycemia of mild to moderately severe degree occurred in all patients, in some as frequently as once or more each day. In three patients hypoglycemia was severe, causing nocturnal convulsive seizures or periods of irrational, aggressive, and abusive behavior. One patient feared hypoglycemia so much that she refused to leave her home lest she come to harm elsewhere.

When treatment was changed to include crystalline insulin only, hypoglycemia was sometimes noted but usually abated with adjustment of dosage. Ten patients described fewer and/or less severe episodes of hypoglycemia.

The average insulin dose was reduced from 49 units before to 42 units during treatment with crystalline insulin. The mean crystalline insulin distribution for all patients was 34% before breakfast, 17% before lunch, 31% before supper, and 18% between midnight and 2 a. m. The average single dose of crystalline insulin was 10 units, and the highest single dose in any patient was 35 units. The small size of each dose undoubtedly contributed to diminished frequency and severity of hypoglycemia. Insulin lipodystrophy present in two patients prior to treatment with crystalline insulin showed no perceptible worsening in spite of the multiple injections.

Of the 14 patients studied, only 4 failed to show improvement in the control of their diabetes. In two of the four data were inconclusive, and in the remaining two there was no improvement. One of the latter patients was emotionally incapable of adhering to a dietary program and ate in an erratic and inconstant fashion, refusing both medical advice and psychiatric counsel.

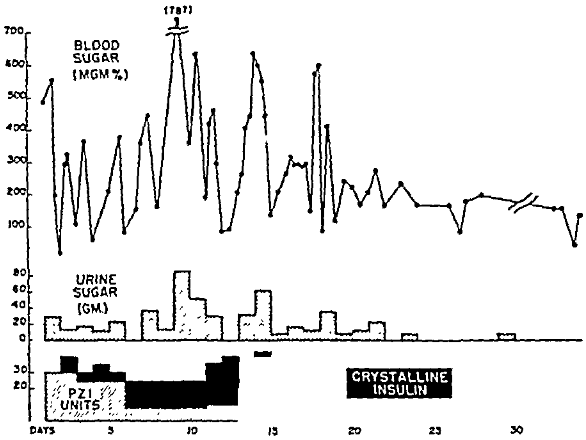

Fig. 1 (case 3).—Graphic record during hospitalization of 21-year-old woman, showing wide oscillations in blood sugar level during treatment with protamine zinc and crystalline insulins. Note diminution in variability of blood sugar level and fall in glycosuria soon after start of treatment with crystalline insulin alone.

Comment

The use of divided daily doses of crystalline insulin has been satisfactory in ameliorating the severity and frequency of hypoglycemia and diminishing fluctuations of the blood and urine sugar contents in patients with very labile diabetes.

The dose of insulin given between midnight and 2:00 a. m. presents the greatest inconvenience to the patient. Some patients have elected to postpone their bedtime until after the midnight injection. Others have retired earlier after filling the insulin syringe and placing it at the bedside with an alarm clock. On being awakened at the proper time they administer their insulin and go back to sleep. Although multiple daily insulin injections are somewhat inconvenient, only one patient in this group expressed a complaint about it, and no patients insisted on resuming their previous insulin program.

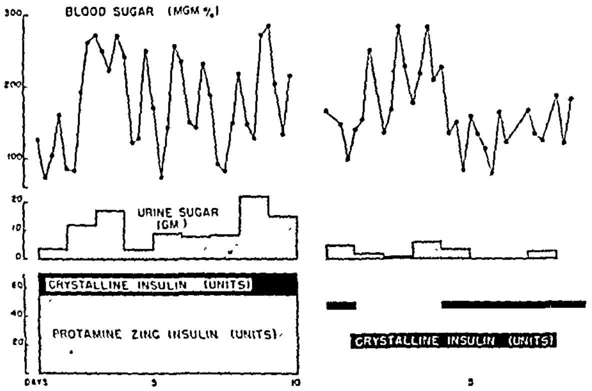

Fig. 2 (case 6).—*Findings similar to those in figure 1 are seen for 29-year-old woman. In addition, total crystalline insulin required is less than total of protamine zinc and crystalline insulin used at first.*

The small size of each individual dose of crystalline insulin provides several advantages to the patient in addition to maintaining better blood and urine sugar levels. Hypoglycemic episodes are easily detected, do not last long, and respond readily to treatment. The 40-unit strength of insulin may be used almost exclusively, affording greater accuracy in measurement than is possible with a more concentrated preparation. It is evident that in some patients the salutary effects of this regimen may not be maximal for several months, and one need not be discouraged by failure to achieve success promptly.

While patients with labile diabetes mellitus are often young or have had an early onset of diabetes mellitus, age does not exclude lability. One of the patients studied was 58 years old and developed diabetes at 52 years of age. Seven patients were over 30 years of age, although the onset of diabetes occurred after that age in only two.

Summary

Of 14 patients selected because of unusual lability of the blood sugar level and failure of long-acting insulins to control symptoms of diabetes satisfactorily, 10 were improved, results in 2 were inconclusive, and 2 were unimproved by the use of multiple injections of crystalline insulin alone.

TABLES OF AVERAGE WEIGHT AND HEIGHT OF AMERICANS AGED 65 TO 94 YEARS

RELATIONSHIP OF WEIGHT AND HEIGHT TO SURVIVAL

Arthur M. Master, M.D., Richard P. Lasser, M.D.
and
Gloria Beckman, B.A., New York

Provisional standards of height and weight for persons 65 to 94 years of age are here set up on the basis of data from 2,925 men and 2,694 women. All subjects were ambulant, all lived in the community, and all were free from evidence of cardiovascular, renal, or other disease. Weights and heights were measured in stocking feet, and weight included that of light undergarments. For men between the ages of 65 and 69 years the range of stature was from 154 to 185 cm. (61 to 73 in); the average man of this age group was 173 cm. (68 in.) tall and weighed 72 kg. (159 lb.). For women between the same ages the range of stature was from 147 to 175 cm. (58 to 69 in.); the average woman was 160 cm. (63 in.) tall and weighed 64 kg. (141 lb.). In both sexes and at all heights the average weight became lighter with advancing age. Height, unlike weight, virtually did not diminish with further aging. The authors emphasize that the published figures are averages of actual measurements rather than optimal or ideal figures.

This communication will present the results of a survey of height and weight in persons in the healthy population of the United States between 65 and 94 years of age. From these data a table has been developed for this older population, showing average weight in relation to height among men and women in successive five-year age groups. From analysis of the changes in height and weight distribution with advancing age, some inferences have been drawn about the relationship of height and weight to survival after the age of 65 years.

The first table should prove useful as a standard of reference in defining the limits of overweight and in studying the association between height, weight, and disease. It may also serve as a guide for weight control in persons of advanced age.

Weight control has become recognized as an important aspect of preventive medicine. Excess weight, with its attendant increased risk of cardiovascular and renal disease, diabetes mellitus, and gallbladder disease, has already been shown by life insurance investigations to exert an unfavorable effect on longevity in younger age groups. As will be shown, it is a factor of increasing importance after the age of 65 years.[1]

Concern with the problems of geriatric medicine has only recently become widespread because of the pressure of the increasing older population. It has been estimated that 80% of persons who attain the age of 40 years will live to be at least 65 years of age. Furthermore, more than one-half of caucasoid men who celebrate their 65th birthday will survive another 12 years, and one-fifth for 20 years. The outlook is even better for women; one-half of those who reach age 65 will live to the age of 80, and one-fifth will celebrate their 88th birthday.[2] There is every expectation that this degree of

Read before the Section on General Practice at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 9, 1959.

survival can be prolonged and health improved by proper attention to such factors as nutrition, physical activity, and mental outlook.

This report represents one facet of a survey of the blood pressure and general health of the older population, conducted by the authors and made possible through the generous cooperation of thousands of physicians throughout the country who furnished these data. The published results of this survey to date have included such observations as that blood pressure rises with increasing weight in both sexes from the age of 65 on but bears little or no relationship to height alone. Blood pressure is related to body build, that is, to the person's weight relative to his height and not to the absolute weight.[3] Women over 65 years of age have consistently higher systolic pressures than men, although their diastolic pressures are practically the same. After 65 years of age blood pressure ceases to rise consistently with age.[4]

Methods

The series on which the study was based was composed almost wholly of caucasoid subjects from all geographical areas of the United States, belonging to all social and economic levels, of various ethnic origins, and engaged in a variety of occupations. All were ambulant, living in the community, and apparently in good health. Persons with histories of cardiovascular or renal disease were excluded.

Height and weight were recorded with subjects in stocking feet and clad only in light undergarments. The weight of these undergarments was not subtracted. The series was divided according to sex and subdivided into five-year age groups. Persons 95 years of age and over were too few in number to be statistically useful.

The average weight at each inch of height was then calculated for each five-year age group according to sex. These crude data showed an orderly but not perfectly consistent progression of weight with increasing height, particularly at the upper and lower extremities of the height range. Therefore, in order to minimize sampling artifacts, the crude data were statistically transformed by use of a "weighted moving average," a statistical technique commonly used for data of this type. The height-weight tables presented here are based on these results. Crude values and the number and distribution of heights and weights in the sample population have been published previously.[5] There were 2,925 men and 2,694 women in the sample.

Table 2.—*Mean Height, Weight, and Body Surface Area in Persons Aged 65-94 Years*

Another grouping of various height-weight classes was formed by classifying all subjects as either tall, medium, or short and then assigning them to one of four weight groups as follows: underweight—at least 10% lighter than the mean in their height group; average—from 9% lighter to 9% heavier; moderately overweight—more than 10% and less than 25% heavier than the mean; and severely overweight—25% or more heavier than the mean of their respective height group. This classification is the one generally used by insurance companies. Its value lies in that it is possible to follow the effects of aging on height and weight in terms of commonly held mental images of body build. The percentage of subjects falling into each weight and each height group was then determined for successive five-year intervals. Details have been published previously.[3]

Results

Table 1 presents the average weight for each inch of height for persons of each sex in five-year age groups. The height range in men between 65 and 69 years of age is from 61 to 73 in. (154 to 185 cm.); in women of the same ages from 58 to 69 in. (147 to 175 cm.). These ranges are maintained up to the ages of 80 to 84 years, when the smaller size of the total sample compels the omission of the shortest and tallest standards because too few observations can be made. For subjects between the ages of 90 and 94 years, values are statistically credible only for those between 65 and 71 in. (165 to 180 cm.) tall in men and 62 to 66 in. (157 to 168 cm.) tall in women. Women consistently weigh less than men of the same height, except for tall women aged 65 to 69 years.

Weight increases with increasing height as the bony frame becomes larger and heavier. However, the increase in weight for each successive inch of height is not constant but rather increases with increasing height. Thus, in men, weight increases by 2 or 3 lb. (0.9 to 1.4 kg.) per inch of increased height from 61 to approximately 68 in. (155 to 173 cm.), whereas from 68 to 73 in. (173 to 185 cm.) the weight increases by 4 or 5 lb. (1.8 to 2.3 kg.) per inch. In women there is an increase of 2 lb. per inch of height at short to average heights and 3 to 4 lb. per inch at the taller heights.

Changes with age in average weight are striking in both sexes, and a decrease in average weight is noted at each inch of height decrease. For example, the average weight of men 70 in. (178 cm.) tall is 167 lb. (75 kg.) at ages 65 to 69, 165 lb. (74 kg) at 70 to 74 years, 162 lb. (73 kg.) at 75 to 79 years, and 149 lb. (68 kg.) at 90 to 94 years. This decrease of 15 or 20 lb. (7 or 9 kg.) in the average weight of surviving persons over a period of 25 years is seen in persons of both sexes and at each inch level of height. By contrast, mean height changes insignificantly with advancing age, being 68 in. at 65 to 69 years and 67 in. (170 cm.) at 90 to 94 years for men and for women 63 in. at 65 to 69 years and 62 in. at 90 to 94 years (160 and 157 cm.).

Table 2 shows the mean height, weight, and body surface area of persons in each five-year age group. The average man aged 65 to 69 years is 68 in. tall and weighs 159 lb. (72 kg.); aged 90 to 94 years he is 67 in. tall and weighs 136 lb. (61 kg.). The average woman aged 65 to 69 years is 63 in. (160 cm.) tall and weighs 141 lb. (64 kg.); aged 90 to 94 years she is 62 in. tall and her average weight is 119 lb. (54 kg.).

Table 3 presents the range of weight variation encompassed by ±10 and ±20% of the average weight at each inch of height. Traditionally, for younger subjects a permissible range of variation has been considered to be ±20% of the average. However, in this older group, we believe that this may be too broad and that ±10% limits may be more desirable. Thus, for the average man 65 to 69 years of age, height 68 in., the range of desirable weight (±10%) would be 143 to 175 lb. (64 to 79 kg.). For the average woman 65 to 69 years of age, height 63 in., the range (±10%) would be 127 to 155 lb. (58 to 70 kg.).

Figures 1 and 2 present a summary of the effect of aging on the distribution of weight. The percentage of underweight, average weight, moderately overweight, and severely overweight persons at each five-year age interval is shown for men in figure 1 and for women in figure 2. These weight groups are defined in the section on methods. Among men the proportion of underweight subjects increases from about 20% at the age of 65 years to about 50% in the oldest group, while moderately and severely overweight men decrease from about 30 to about 10%. Similarly, in women the proportion of underweight subjects increases from about 20% at the ages of 65 to 69 years to 55% at the age of 90 years and over, while overweight subjects decrease from 40 to 10%. The incidence of overweight subjects decreases sharply with advancing age from 65 years onward, whereas the frequency of underweight subjects increases greatly in both sexes.

Comment

As indicated, the table of average weight for persons at each inch of height, and the table of weight range 10% and 20% below and above average, are, to our knowledge, the first of their kind to have been presented in the United States for the age group 65 to 94 years. It is based only on ambulant, apparently healthy subjects without evidence of cardiovascular or renal disease. The number of subjects, 2,925 men and 2,694 women, and the homogeneity and widespread geographical distribution of the sample are, we believe, sufficient to give it considerable statistical credibility.

While this table is the first for the older population, average tables of weight for adults between the ages of 15 and 69 years have been in existence for more than 50 years. Historically, the first of these tables for the United States, known as the Shepherd table, was compiled from a study by the Association of Life Insurance Medical Directors of 1897.[1d] The one which is in general use today was derived from the Medico-Actuarial Mortality Investigation published in 1912.[1a] In 1931 [1a] another large-scale intercompany insurance investigation was made, which indicated that the average weights observed in 1912 had not changed materially during the first quarter of this century. Except for persons aged under 25 years these findings were so similar to the existing tables of 1912 that they were regarded not as a revision but as a confirmation of the previously presented data.

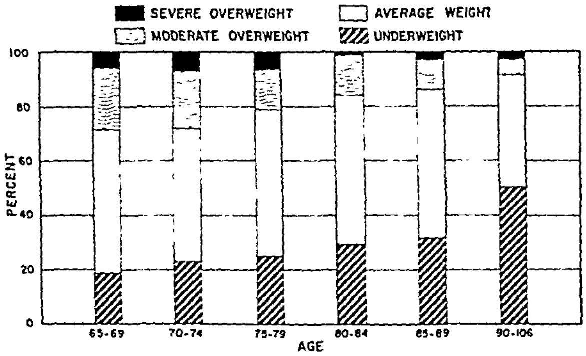

Fig. 1.—Distribution of weight for men aged 65 to 106 years.

In 1957, a height and weight table was presented by Bøe and co-workers,[6] on the basis of a survey of almost the entire adult population of the city of Bergen, Norway. While there were fewer persons aged 65 years and older than in the current study, comparison revealed an interesting observation, namely, that the Norwegian population was heavier at each inch of height than the American one reported here (as much as 7 lb. [3.2 kg.] for men and 15 lb. [7 kg.] for women). This, we believe, indicates the necessity for limiting the applications of such tables to the population sampled.

The decrease in weight with age after the age of 65 years probably can be explained as the additive result of two factors, (1) a loss of body substance, i. e., protein, water, fat, and calcium, which is the physiological accompaniment of aging[7]; and (2) a progressive reduction in the proportion of overweight subjects because of a relatively high mortality among these as compared with the "underweight." Thus, the current survey again emphasizes the favorable survival rate of thin persons.

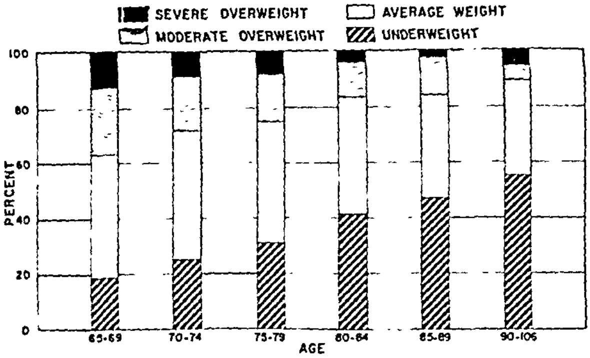

Fig. 2.—Distribution of weight for women aged 65 to 106 years.

The association of even moderate overweight with an excessive mortality rate was first clearly demonstrated by the analysis of death rates among insured persons. Shepherd,[1d] in 1897, in a paper on the relation of body build to longevity, delivered before the Association of Life Insurance Medical Directors, concluded that, as policy risks, "The overweight are clearly less desirable than either the normal or the underweight." These conclusions concerning overweight and excess mortality at ages above 28 years were confirmed by more extensive life insurance studies in 1914 and 1931.[1a] In the 15-to-28-year-old groups, underweight subjects at that time did not seem to do as well as their heavier peers because of a high mortality from tuberculosis and pneumonia.[1] Subsequent studies by Dublin and Marks,[8] Blair and Haines,[9] and McCormick [10] have shown that, in the years since 1929, with the dramatic decrease in deaths from tuberculosis, underweight persons now have the most favorable mortality at all ages, even at the younger ones. Marks [1c] of the Metropolitan Life Insurance Company in 1956 summed up these mortality investigations made since 1897 by saying that ". . . excess mortality was found consistently to be due to the early onset and relatively rapid progression of diseases affecting the circulation, the excessive frequency of diabetes in which vascular breakdown occurs earlier than in nondiabetics and of disorders affecting the liver and gallbladder. The implications of these findings with regard to the penalty of overweight are unmistakable."

It was found that height does not bear any relationship to longevity.[3] This finding contradicted an impression held by some investigators [11] and lay persons in general that tall persons do not have as satisfactory a survival rate as shorter ones.

Regarding the nature of the table of weights by height we are herewith presenting, we wish to add a note in explanation of what is actually represented and its relationship to past tables of height and weight. Our tables of weights are average weight readings which may be contrasted with tables representing "ideal weights." The "ideal weight" may be defined simply as that weight associated with the lowest mortality rate, since we have seen that excess weight and excess mortality are related. Hunter [12] pointed out that the "average" weight is not necessarily the best weight, since it merely "reflects the racial stock, the methods of life, the climate and other conditions."

Ideal weight has generally proved to be considerably less than the average weight at all ages from 20 to 65 years. While such a table of "ideal" weight has been presented for ages 20 to 65,[13] there is no comparable study of those aged 65 years and over. We hope that in the future such a study can be made of the older population. In the interim, we feel that this table can be used to guide the weight of our older population.

Conclusions

A table of average weight at each inch of height, for persons of each sex, in five-year age groups, has been presented for the population between 65 and 94 years of age. This is the first table to be constructed for this group. The current study involved apparently healthy subjects in the United States. The data should prove valuable in research on the relationship of weight to disease and as a guide for weight control in the older population. Weight increases with increasing height, as the bony frame becomes larger and heavier. After 65 years of age mean weight decreases progressively with advancing age in both sexes at every inch level of height. This decrease is due to loss of body substance and to reduction in the proportion of overweight subjects by a relatively higher mortality.

From the age of 65 to that of 94 years, overweight men decrease from 30 to only 10% of the population, while underweight men increase in frequency from 20 to 50%. At the same ages, overweight women decrease from 40 to 10%, while underweight women increase from 20 to 55%. This emphasizes the favorable survival rate of underweight persons. In the older age group, ±20% variation from the mean is too broad a criterion for normal; only a ±10% variation in weight should be considered healthy. There is little or no change in average height in persons aged from 65 through 94 years. Tall persons seem to have as satisfactory a survival rate as shorter ones.

125 E. 72nd St. (21) (Dr. Master).

Messrs. E. A. Lew, actuary and statistician, of the Metropolitan Life Insurance Company, and Richard V. Kasius, staff member of the Milbank Memorial Fund, assisted in the preparation of this report.

IMPACT OF SPACE EXPLORATION ON BIOLOGY AND MEDICINE

Clark T. Randt, M.D., Washington, D. C.

Space exploration offers an unparalleled opportunity for the productive integration of the physical and biological sciences directed toward expansion of our knowledge of the universe. Means of improving human tolerance of the expected combined stresses involved in space flight and provision of adequate life-support systems will be necessary to allow man to lend his unique capabilities to accomplishment of the tasks ahead. New knowledge of extraterrestrial environmental effects on all forms of life will result from studies of comparative biology on the broadest scale and will undoubtedly lead to further understanding of the fundamental laws of nature.

Basic human drives for pioneering and conquest can find acceptable expression in extraterrestrial exploration. It is unmistakably clear that our civilization cannot survive a thermonuclear conflict. The expression of aggressive drives in war has repeatedly supplied an impetus for unusual increments in the growth of the arts and sciences. A historical review of intellectual progress and concomitant technological advance gives reason to expect that expanded knowledge of the universe will produce an unprecedented burst of creative activity in biology and medicine as well as in the physical sciences and engineering.

Role of Man in Space

Only with the advent of high-altitude high-speed operations within the past two decades has man's role in flight become the subject of intensive study in military aviation medicine, resulting in special adaptation of aircraft and equipment to the pilot. These developments have also brought to the fore the necessity for more discriminating selection of highly intelligent, inherently capable persons for extensive training prior to being given control of intricately designed high-powered vehicles.

At the threshold of the Space Age, questions related to man's participation in space flight and exploration have already assumed significant proportions. Suggestions have been made that reveal doubt in some quarters as to the propriety and ultimate usefulness of man's being propelled into outer space. From some of the same sources the space effort, in general, has been regarded as no more than large-scale participation in an international pyrotechnic display involving sizable sums of the taxpayer's money. The scientific, political, economic, and sociological implications of such statements are unfounded. My remarks are directed to the scientific aspects of space exploration as they relate to biology and medicine.

Initial serious interest in man's role in space has been concerned with the utilization of his unique characteristics which allow him to absorb a wide variety of observations, to process this data, to store it as memory, or to use it to exercise judgment in decision-making in a way that could not conceivably be done by any man-made device. Such human qualities as persistence and resourcefulness as well as the relative reliability of complex human systems further indicate the need for man's inclusion in the operational aspects of space flight and exploration.

Research.—Research and development designed to comply with the requirements of manned space flight are now in progress. Military aviation medical personnel are making a major contribution in this area. Their knowledge and experience, gained over the last 20 years, provide a substantial base on which to build for the future.

The immediate needs of space flight are for conquest by man, within the limits of his tolerance, of the stresses of acceleration, vibration, temperature, weightlessness, and impact during the launching, flight, and reentry phases. Life-support systems, insuring survival by maintaining the vehicle environment within physiological limits as to pressure, oxygen supply, humidity, carbon dioxide concentration, and waste removal, are essential. Means of escape in case of impending disaster must be provided. Instrumentation allowing for recording and telemetry of data concerning the function of man and these systems in flight are being further developed. These are some of the prerequisites for determining man's capability of performance which will make it possible for him to lend his unusual talents to the problems at hand. These factors must be projected into the near future when larger payloads and flights of longer duration are feasible. Regenerative systems for support of life which use solar energy to provide fluid, food, and gaseous requirements will then be necessary. Radiation hazards must be further delineated and overcome.

From the National Aeronautics and Space Administration.

Read in the Symposium on Medical Problems in the Jet and Space Age before the Section on Military Medicine at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 9, 1959.

Means for management of possible meteorite damage and arrangements for in-flight maintenance of equipment over periods lasting weeks or months, or more, must be developed.

Man's nervous system is the key to his usefulness in the space setting confronting us. With the present emphasis on survival, no vital system, including the heart, circulation, or respiratory mechanism, has been overlooked, but relatively little effort has been made to assess more than the most fundamental life-supporting functions of the brain. The role of the nervous system in the rapid adaptation of the body to the internal and external environment has been established. Longer term adjustments involve hormonal influences which are also under neural control. The physiological concomitants of more complex levels of behavior and performance are little understood. One of several approaches to this problem involves intensified study of the nature of the varied input from sensory receptors.

Weightlessness and other aspects of sensory deprivation have special pertinence in anticipation of manned space flight. More information about the integration and elaboration of the afferent input as it modifies the neural substrate of abstract thought, learning, memory, and emotion is urgently needed. Perceptions are likely to be altered by long-term application of unusual forces on the body sensors, as well as by isolation, fatigue, emotional reactions, and long-duration modifications of cyclic light-dark, sleep-activity, and temperature rhythms. Study of animals and man subjected to real or simulated space environmental conditions offers a unique opportunity to gain fundamental information relating to consciousness, orientation, mentation, emotional reactions, and motor coordination.

Integration of the Sciences

A number of new problems of great complexity and interdependence relating to the fields of biology and medicine arise in anticipation of manned space flight and exploration. An unparalleled opportunity for productive integration of the physical sciences, engineering, and the biological sciences is presented and must be comprehensively exploited to produce the desired results. Such integration has been notably difficult to accomplish in the past. The traditional organization of the biological sciences is as follows: biophysics, biochemistry, physiology, and psychology. Reorganization of this as well as of the physical science and engineering disciplines, in vertical fashion, to be applied to the problems to be studied, will provide the best opportunity for bringing each discipline to bear on the major areas under investigation. Restriction of effort to immediate problems such as acceleration and other forms of stress, radiation effects, and life-support systems would not satisfactorily provide the scope or flexibility necessary for meeting the requirements of the future. Studies from a molecular to an intact organism level, where appropriate, with use of an interdisciplinary approach, are likely to be most productive.

Coordinated efforts in "bioengineering" are now in progress which are concerned with development of a suitable space vehicle environment and other life-support systems consonant with present and anticipated payload capabilities. The limits of tolerance for various physiological stresses and means of adaptation to remain within these boundaries are being determined on centrifuges, in altitude chambers, and by other flight-simulating devices. In this process, a number of technological advances related to designing vehicles to fit men and training men to use them are being accomplished.

The broad application of biophysics is relevant not only to problems of radiation and physiological instrumentation but also to the cardiopulmonary aspects of acceleration and weightlessness. Long-term results of alterations in pressure, gas exchange, humidity, and temperature are worthy of consideration. Investigations of more extensive use of computers for the processing of biological data are appropriate.

Metabolic studies are concerned with cellular division, nutritional requirements, and utilization of energy of a variety of organisms, including man. Chemical and photosynthetic processes are expected to provide regenerative systems to sustain life over long periods of time in a closed ecologic system. These closed systems introduce special consideration of intoxicants and contaminants which could be injurious to living organisms. The possible uses of controlled hypothermia are being explored with regard to reduction of metabolic requirements for food and fluid as well as protection from various stresses, including those in the psychological sphere.

Studies of extraterrestrial environments and their effects on biological adaptation and genetics are of particular interest. Botanical and zoological investigations from a microbiological level to man have pertinence to the exploitation of an entirely new dimension for the observation of biological effects.

Results.—It is not part of scientific investigation to predict the specific utility of the results. However, there is no reasonable doubt that space exploration offers a new vantage point for observation of the effects of environmental factors on all forms of life, which will provide numerous important applications of a practical nature relative to biology and medicine. Absence of gravitational force, extreme alterations in remote atmospheric composition and pressure, radiation, and other energy fields affect organisms of all degrees of complexity, including man. Development of means of measuring and surmounting certain deleterious influences will be forthcoming, which will probably be applicable to many problems we now face on earth. The unfamiliar features of this unexplored environment can be expected to serve as tools for revealing the nature of many hitherto unexplained biological phenomena. Ultimately, it is likely that extraterrestrial living organisms will be discovered as well as physical and biological resources to support life as we know it.

More comprehensive knowledge of the environment in space, on the moon, and on planets undoubtedly will have a profound influence on man and other forms of life on earth. The horizon, expanded to include progressively more of the universe, can be expected to provide intense stimulation with resultant significant advances in biology and medicine.

PHYSIOLOGICAL ASPECTS OF HYPERGRAVIC AND HYPOGRAVIC STATES

APPLICATION TO SPACE FLIGHT

Major Julian E. Ward (MC), U. S. A. F.

The planning of a circumterrestial orbiting space flight of a human passenger includes a mission profile to accommodate the inherent structural limitations of the passenger and life-supporting subsystems. During launching, reentry, and recovery phases of a man-missile flight, the man will be in gravitational environments with which he is not familiar, since the force on the earth is 1 g. Should an escape from the missile be necessary, during its powered flight (4 to 10 g), decelerating forces of 40 g will be affecting the capsule. A man can tolerate a force of 8 g for only 90 seconds. The functional problems of the human body while in orbit, a zero-gravity environment, concern neurological mechanisms, spatial orientation, motion sickness, cardiovascular function, gastrointestinal activity, excretion, and skeletal muscle activity. The value of the physician members of the space-capsule-design team is obvious, and one of the important objectives of the manned space flight will be to collect psychophysiological data.

The missile inventory of the world powers now includes vehicles with sufficient thrust to place into circumterrestrial orbit a human passenger with life-support subsystems. The United States National Aeronautics and Space Administration has announced preliminary plans for one such vehicle, Project Mercury, based on the use of the Air Force-developed Atlas booster. The planning of any such venture requires an understanding of the dynamic forces produced in such a flight and the manner in which they alter physiological function. The mission profile must be shaped around the inherent structural limitations of the human occupant. In this brief outline of the so-called hypergravic and hypogravic states which will be encountered by biological payloads, discussions will be directed toward the use of a hypothetical vehicle with intercontinental ballistic missile (ICBM) energy characteristics. A conceptual rather than a didactic approach to such stresses will be given, with estimates of human limitations for certain aspects of the mission profile.

The man-missile flight will impart other than 1-g fields to the occupant throughout launched escape from the vehicle in powered flight and orbit and during the reentry and recovery phases.

First Phases

Boost.—In order to markedly improve tolerance to accelerative forces the capsule pilot-subject will be seated with the long axis of his body perpendicular to the line of flight, thus necessitating the assumption of a prone or supine position while the vehicle is on the launch pad. Centrifuge studies by Bondurant and co-workers[1] of the Air Force Aeromedical Laboratory have revealed that, in the optimum position, the vector of force should be applied from anterior to posterior at 65 degrees to the long axis of the trunk, while the lower extremities are maintained flexed at a 90-degree angle at hips and knee. Large liquid-fuel engines characteristically impart a slow increase in acceleration until

Read in the Symposium on Medical Problems in the Jet and Space Age before the Section on Military Medicine at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 9, 1959.

a peak of usually less than 10 g is attained. An instantaneous or brief period of coasting may follow until second-stage ignition occurs, which, with liquid-fuel engines, reproduces a g-curve closely resembling that of first-stage ignition. Human tolerance to an 8-g exposure is roughly 90 seconds. Since burning time after achieving 4 g is rarely more than one minute, such lift-off accelerations are easily tolerable.

Escape.—The most hazardous portion of the entire flight may occur during the boost acceleration period. Should the engine or guidance systems, or both, fail, deceleration forces exceeding 40 g may be imparted to the capsule. Therefore, careful attention is given to the forced shaping of such an emergency trajectory by escape rockets or extendable deceleration dive flaps, or both. The most critical escape period for a two-stage vehicle is near the midburning time of the second stage.

Orbit

Once a satellite orbit has been established, the mission may require one or more rotations around the earth, which would subject the pilot to a period of "zero-gravity" varying from one and one-half hours to many days. Although interest in the phenomenon of weightlessness has virtually paralleled interest in space travel, it is only within the past decade that anything more than theoretical analysis has been attempted. During this period, experiments involving the brief exposure of biological specimens, including man, to the weightless state have been devised with use of parabolic flights by jet aircraft. Even shorter exposures have been produced and their effects studied during free falls from high towers. Finally, ballistic missiles have yielded many minutes of weightlessness for animal subjects; a relatively prolonged exposure was achieved in the canine experiment of the U. S. S. R.'s Sputnik 2.

In spite of this limited experience, we are able to foresee, to some extent, the effects and potential problems of weightlessness on biological systems and components. Also, we can foresee the requirement for the development and improvement of certain mechanical contrivances to assist man in adapting to this subjectively new milieu. The physiological parameters which may be significantly affected by exposure to a 0-g field include neurological mechanisms, spatial orientation, motion sickness, the cardiovascular and gastrointestinal systems, body waste elimination, and skeletal muscle activity.

Concern has been voiced by many medical investigators over the potential effect of sudden withdrawal of the shower of sensory impulses generated by the graviceptor transducers of the body. However, there are many other sources of "neurological background noise" which may be ordinarily blocked out by the constant flood of "1-g" body positional information pouring into the central nervous system. This sensory output from the integumental surface and viscera may substitute for the normal gravity proprioceptive sensory outpourings; training of subjects by artificial reinforcement of skin pressure clues may offer an adequate solution. Depth and restfulness of sleep under these conditions are under inquiry; drugs may be required to give restful, fatigue-relieving sleep.

Disorientation as a response to the weightless state has been reported several times under both operational and experimental situations in parabolic maneuvers. In virtually all such cases, it appears that these incidents resulted from attempts at "free float." Such difficulties are generally obviated when the subject is well restrained, with extremities resting against solid objects. However, unrestrained locomotion about a space cabin may cause some degree of disorientation. Cabin design and coloring to indicate "floor" and "ceiling" will assist in maintaining spatial orientation by visual means.

Individual susceptibility to nausea and vomiting under the relatively simple and experimentally reproducible conditions of ordinary aircraft flight is poorly understood. Any attempt to derive definitive conclusions from the complex motion situation prevailing in the production of parabolic trajectories by jet aircraft is therefore fallacious. But cognizance must be taken of the report of illness in about one-third of subjects exposed to such flight conditions. Most, although perhaps not all, of these responses may be explained by such factors as the nature of changing acceleration fields on entry and exit from these maneuvers, the flying experience of the subjects, and incompetence of the stomach's cardiac sphincter. The extent to which the weightless state alone influences the incidence of this sickness will remain in doubt until actual manned orbital flights are completed.

One interesting fact reported from the Sputnik 2 experiment was the unusual lag in return to normal of the pulse rate of the canine passenger from the tachycardia induced during vehicle boost. Some degree of overfilling of the right heart, shifts of pooled venous blood, and minor changes in electric and anatomic cardiac axes may occur, but there is no reason to believe that cardiovascular instability will result. There is certainly more basis for predicting cardiovascular symptoms in subjects thoroughly "acclimatized" to zero "g" when they return to a normal accelerative environment on earth. Von Beckh[2] has recently demonstrated that lowered positive g tolerance may result from even brief exposures to weightlessness, and this may be of great significance during a reentry maneuver after a period in orbit.

Experimental observations[3] of the deglutition mechanism under weightless conditions have indicated that with normal mastication of solids, swallowing of the semiliquid bolus of food presents no problem. Poorly chewed solids tend to present difficulty in swallowing; indeed, these particles may occasionally float above the palate, and the danger of aspiration is real.

As mentioned previously, the competence of the cardiac sphincter of the stomach under these conditions is dubious. During parabolic jet maneuvers a regurgitation of stomach contents has resulted when a blow or even pressure is imparted to the abdomen; this is most often associated with ingestion of a large volume of fluids.

Many years ago Hoelzel[4] completed a comprehensive study of the passage of inert materials through the intestinal tract in which materials with widely varying densities were surveyed. It was learned that the rate of passage of these materials was an inverse function of density. Therefore, under a 0-g field, food passage time may be slightly reduced. When one considers the length of the intestine and the surface tension of the semiliquid intestinal bolus (i. e., the opportunity for absorption), it would appear that absorption of metabolites offers no problem.

Elimination of body waste solids and liquids is a function of elasticity of vesicular and visceral tissues, voluntary muscles, sphincter action, and, to only a slight extent, gravitation. In a study[5] of 26 subjects, micturition was demonstrated to be possible in the weightless state. However, 58% of these subjects, on attaining zero gravity, noted a diminution or total absence of the sense of urgency.

Studies[6] of psychomotor performance, particularly eye-hand coordination tasks, have indicated that compensation for the loss of upper-extremity weight is rapidly learned. Manipulation of the cockpit controls and environmental components by the space pilot is therefore not anticipated to be a difficult problem. Learning new locomotion techniques will undoubtedly be more difficult because of the relatively greater mass of the lower extremities.

It is apparent that we cannot assign any scientifically supported time limitation to weightless exposures for man. Evidence presently indicates that although a few persons may consider the experience an intolerable one, most will find it welcome relief from the oppression of lift-off forces.

Reentry

Prior to initiating the reentry sequence the pilot should rotate either the entire vehicle or his seated position through 180 degrees, so that g forces of reentry will be applied in the same direction as in the initial boost phase. If the pilot does not accomplish this maneuver his g time tolerance in the range of 6-10 g will be decreased about 30%.

For enhancement of vehicular dynamic stability, high drag–low lift reentry bodies must be spun, with the spinning axis coincident with the axis of flight. The anatomic axis of rotation, the speed of rotation, and the superimposed reentry g will all affect the time tolerance for spin. The greatest tolerance for spin is achieved with the center of rotation at the heart, where, without superimposed reentry deceleration forces, 100 seconds at 80 rpm is tolerable.[7]

As the space vehicle begins to dip into the sensible atmosphere on the return voyage, the decelerative forces resulting must be again programmed so that the delicate balance between the angle of reentry, the thermal pulse, and g pulses overstress neither the heat control mechanism of the reentry body nor the structural tolerance of the man. For any given reentry body a set of curves can be derived.

During the first several moments of atmospheric encounter a new stress may be imposed by the vehicle, which may begin to tumble slowly and then, orienting itself, swing through constantly decreasing arcs of amplitude with increasing frequency. The g loads imposed on any particular organ system of the subject will be derived as functions of their distance from the vehicle's center of gravity as well as of the amplitude and frequency of the oscillation. At last the vehicle settles down for its final straight-line plunge.

Finally, the mission nears completion as a parachute is deployed and the vehicle lands on earth or water. The effect of these abrupt shocks on the human body will depend on the rate of application, magnitude, direction, and duration of the force. Stapp[8] has demonstrated with rocket-sled linear decelerators that man's tolerance is not exceeded by up to 50 g applied at 500 g per second for less than a 0.2-second duration. A more rapid rate of application, e. g., 1,500 g per second, reduces the limit of human endurance to 40 g for less than a 0.2-second duration. Therefore, parachute deployment and ground impact must be regulated by parachute design in the former and controlled structural collapse or shock absorption devices, or both, in the latter.

The value of the physician member of the space capsule design team is apparent and needs no further emphasis. The various stresses of space flight, arising from the environment of space itself and from the stresses induced by the space vehicle, may affect many organ systems, often in a complex fashion. One of the most important medical objectives of manned space flight will be to collect additional psychophysiological data so that we may further define and refine the envelopes of human tolerance, rather than remaining cognizant only of the presence of life, or the time of death, of the space crewman.

Dr. John Sellers, Space Technology Laboratory, Inglewood, Calif., assisted in the preparation of this report.

MEDICAL ASPECTS OF AMBIENT RADIATIONS OF EXTRATERRESTRIAL SPACE

Col. Paul A. Campbell (MC), U. S. A. F.

If man is to travel above and beyond the earth's atmosphere he will have to shield himself from radiations to which he is not ordinarily exposed. Three types of radiation here described are the primary cosmic radiation, the secondary cosmic radiation, and the two Van Allen bands of high-speed particles circulating about the earth's geomagnetic equator. Beginning at about 650 km. (400 miles) above the earth, radiation of the Van Allen type reaches intensities of 10 to 100 r per hour, which would be fatal within 30 days to more than half of a number of human subjects exposed to it for two days. An important problem in space travel, therefore, is that of circumnavigating the two zones of Van Allen radiation or of devising shields within allowable weight limits.

Extraterrestrial space abounds with energies of various sorts, potential, kinetic, and electromagnetic, in quantities and intensities that tax our powers of comprehension. It can be generalized that the radiant energies of space run the entire gamut of the eletromagnetic spectrum (fig. 1), extending from the radio waves through the infrared, the visible, and ultraviolet portions, and thence through the x-ray, gamma-ray, and cosmic-ray regions. In addition there is particulate matter of a wide range of speed and energy.

The sources of the radiation can probably be best visualized if one considers our earth, its relatively thin atmospheric sheath, and its magnetic field to lie within the sun's coronasphere, being bathed in the streams of particulate matter and radiant energy emanating from its tremendous nuclear reactions. In turn, the sun and its planetary system can be considered to be only an infinitesimally small portion of the groups of many suns and systems of our galaxy, the Milky Way. Shapley[1] stated that there are 100,000 or more stars similar to our sun in the Milky Way system. Each of these suns spews its particles and radiations, some of which are in violent interplay with those of our sun's coronasphere and with those of one another. To extend this concept, our Milky Way galaxy is only one of millions of other galaxies of the expanding universe whose energies add to this almost inconceivable cosmic interplay. Huge gas clouds, with their swirling magnetic fields, within these various systems act as Gargantuan accelerators or traps, imparting greater speeds or slowing or trapping the particles and the energies, as the case may be.

The earth's atmospheric mass and magnetic fields have in the past shielded the surface of the earth and those who dwell on it, to a degree which at least renders it habitable, from these cosmic materials and energies. Only portions of the radio bands, the infrared and ultraviolet areas, and almost all of the visual range of the electromagnetic spectrum are allowed to pass through. Even these are attenuated and dispersed in varying degrees. They are necessary to life as we know it. It is interesting that man, living under the earth's atmospheric canopy, has, through scientific diligence and industry, developed electronic, photographic, optical, chemical, and other sensors capable of piercing the shield and measuring the energies of space which he cannot himself sense. The atmospheric filtering effect,

Chief, Space Medicine Division, School of Aviation Medicine, Randolph Air Force Base, Texas.

Read in the Symposium on Medical Problems in the Jet and Space Age before the Section on Military Medicine at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 9, 1959.

which has made the evolution and the existence of life on earth possible, is produced by water vapor, ozone, oxygen, carbon dioxide, and such particulate matter as smoke.[2] The terrestrial magnetic fields repel, deflect, or trap many of the energies and particles which would be hazardous were they to strike our atmosphere and our earth with unattenuated force.

Hazards for Man

As new sciences of propulsion carry man beyond the benevolent atmospheric and magnetic shield, he will for the first time be exposed to unattenuated cosmic energies and particles and will be required, through his own ingenuity and resources, to furnish substitute shielding or a substitute for shielding. His ability to shield himself effectively, or possibly to avoid the energies and particles through artful navigation or repulsion, will be one of the most important final determinants of human participation in space operations.

Examining the electromagnetic spectrum from the viewpoint of extra-atmospheric operations (fig. 1), the areas of longer wave lengths embracing the radio waves seem to have no biological significance until the infrared or heat frequencies are approached. The unattenuated heat of the sun striking the exposed half of a space vehicle would, under proper circumstances, heat the surface to something approaching the solar constant of 1.94 calories per minute per square centimeter, while the unexposed shadow side would be in an area approaching absolute zero. However, in space, temperature as such loses its significance, since there is no atmospheric transmission of heat. Experience with the satellites has demonstrated, however, that proper coating of the surfaces can attenuate the temperature effects sufficiently to hold the interiors within a habitable range. Properly controlled heating and air conditioning which would not represent prohibitive weight could then carry the crew compartment into the comfort range. According to Hibbs,[3] satellite shell temperatures in the missiles Explorer 1 and 2 ranged from —25 C (—13 F) to 75 C (166 F), while the interior was held to a range between 0 C (32 F) and 35 C (95 F), a habitable range.

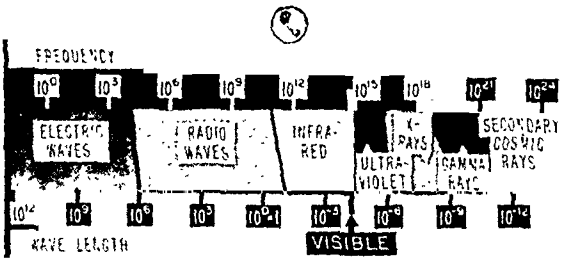

Fig. 1.—Electromagnetic radiations of space: electromagnetic spectrum. Wave lengths are given in centimeters; frequency is in waves per second.

The great heat of the sun's rays unattenuated by the atmosphere of the earth will, through the use of solar heat generators, possibly give us an important energy source, especially for space stations or extraterrestrial colonies. Through this abundant energy source the soil of, let us say, the moon, might be cracked into its basic constituents, among which we hope are oxygen and either water itself or the constituents of water. This energy might also be used in the breaking down of urine and its reconstitution into usable water, as well as the incineration of fecal material into usable materials.

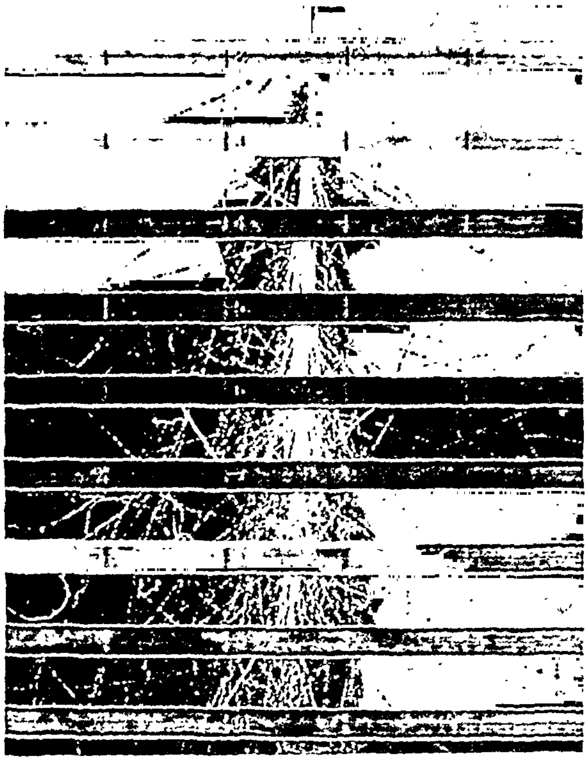

Fig. 2.—Effect of cosmic primary passing through layers of lead 0.5 in. in thickness, showing what happens when particles collide. Cosmic ray enters at top, strikes lead plate, and creates shower of high-energy electrons, simulating reaction as it occurs in space.[4] (Reprinted from *Think*, with permission of author.)

The visible and ultraviolet area of the spectrum can be adequately shielded against by proper choice of window materials and the types of shielding which would be inherent in a well-designed space vehicle. However, there will be a new visual experience to cope with in that all reflecting surfaces will, in proportion to their reflecting ability, reflect the more or less unattenuated light of the sun, and, in the case of exterior reflections, this will be against the black background of space. Light adaptation here will be a factor. Brightness contrasts as high as 1 to 60,000 may be present above the atmosphere.

Portions of the visible light band are necessary for the process of photosynthesis. This process may some day be important as a biosynthetic gas ex-changer and may use algae and plants to take the astronaut's expelled carbon dioxide and convert it into oxygen. In this process starch is manufactured and multiplication of the algal cells or growth of the plants occurs. The simplified chemistry is as follows.

$$CO_2 + H_2O + \text{radiant energy} \rightarrow \text{starch } (C_xH_xO_x) \text{ or sugar} + O_2$$

Weight and capacity restrictions may curtail the use of biosynthetic gas exchangers to space stations or such colonies as a lunar colony. The state of this aspect of science is rapidly improving and may some day be important to us in the achievement of the exploration of space.

Problem Areas

The serious biological problems begin to occur as we enter the areas of higher frequencies and of shorter waves and the various phenomena resulting from the rest of the spectrum, since simple shielding here is no longer effective. Our knowledge is still incomplete in this range, and opinions are, for the most part, conjectures. In the light of present knowledge—and it must be pointed out here that our knowledge is changing from day to day, almost from hour to hour—it seems that three areas can be identified: the so-called Van Allen type of radiation, the cosmic secondaries, and the cosmic primaries. These cannot be identified as discrete spectral areas but they can be identified as discrete problem areas. For purposes of explanation it would be best, at this point, to depart from the spectral order and discuss cosmic primary radiation.

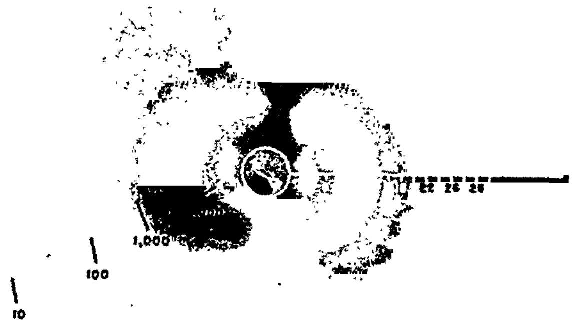

Fig. 3.—Van Allen radiation belts. Horizontal scale at right is in miles of altitude. Diagonal scale to left is in counts per second registered by Geiger counters on Pioneer. Data and adaptation from Van Allen.[8]

Cosmic Primaries.—The cosmic primaries appear to be a mixture of stripped-down atomic nuclei, ranging from protons through iron (z.=26) and possibly even heavier elements. The various nuclear species appear to be present in the flux of particles in proportion to their relative abundancies in the universe.[4] They possess energy measured in billions of electron volts, and the particles are capable of producing nuclear disintegration. Secondary rays, tertiary rays, and mesons are produced by impact with our atmosphere or other material. A remarkable example[5] has been photographed by Prof. Bruno Rossi of the Massachusetts Institute of Technology (fig. 2), showing a hit penetrating a series of 0.5-in. lead plates in a cloud chamber. There are still gaps in our knowledge of the biological effects of primary cosmic particles, but it is believed that they act similarly to radiation of the alpha-particle type, with quick energy dissipation and resultant high concentrations of ion pairs along short tracks.

Primary cosmic particles are repelled or deflected by the earth's magnetic field, and consequently the number striking the atmosphere or the surface of the earth varies greatly with geomagnetic latitude. The greatest geomagnetic attenuation effect is thus in the equatorial regions, while the least is in the areas of the magnetic poles. The energy required to penetrate the equatorial field is greater by a factor of 4 to 6 than at latitude 60 degrees north. Thus one must assume that orbital travel in the vicinity of the earth, crossing the magnetic poles, will be more hazardous from the standpoint of cosmic primaries than it will be at equatorial orbits. As will be pointed out later, this is almost the exact antithesis of the situation produced by the Van Allen type of radiation.

Just how serious is the primary cosmic ray hazard? Much study has been devoted to the realistic assessment of the hazard by Schaefer,[4] Shepherd,[6] Simons,[7] Eugster,[8] and many others. An assessment must consider the statistical distribution of hits. Some areas of the nervous system, the genetic system, or the lens of the eye may be more vulnerable than others. The duration of flight, the distance factor, and the geomagnetic orientation of the flight all have bearing, as do such factors as the type of shielding, solar flare activity, and atmospheric density. The matter is extremely controversial, but I believe the consensus is that primary cosmic radiation will probaby not limit human participation in space flight of the type and extent we may visualize in the readily foreseeable future.

Secondary Cosmic Radiation.—Secondary cosmic radiation results from the effects of the heavy primaries, with their huge energies, striking air particles at the top of the atmosphere and producing cascades of radioactive rubble. For purposes of this discussion, which must be limited to the biological problems of space travel, the secondaries produced by interaction with the atmosphere can be glossed over rather lightly, since their major distribution is limited to altitudes between 60,000 and 90,000 ft. which will be penetrated so rapidly during both flight exit and reentry as to pose no serious problem.

Van Allen Type of Radiation.—This, then, brings us to our final enigma, the intense bands of so-called Van Allen type of radiation. Although previously predicted by a few, it was only brought into sharp focus by the measurements "beeped" back by the Explorer satellites 1, 3, and 4, and confirmed by the Pioneer 1, 3, and 4. At the time of the writing of this paper, knowledge remains scanty. There appear, however, to be two bands of high concentrations of high-speed electrons or protons, or both, circulating about the earth's geomagnetic equator (fig. 3). They are believed by most of the Van Allen group to be particles of solar origin, trapped by the earth's electromagnetic field and varying with solar eruptions. Some investigators, however, feel that particles in the inner belt may be produced by radioactive decay of neutrons, resulting from an interaction between cosmic radiation and the materials in the top of the atmosphere. Van Allen's[9] tentative explanation is something like this: The particles originate in the sun and in some manner are injected into the earth's magnetic fields, where they are deflected into corkscrew-like trajectories around the lines of force and trapped. As they spill over in the auroral zones they produce auroras, magnetic storms, and related phenomena. They may produce air glow and may account for some of the high temperatures noted in the upper atmosphere.

Measurements indicate maximum radiation levels to be between 10 and 100 r per hour, depending on the so far undetermined proportion of electrons and protons. A human being exposed for two days at a rate of 10 r per hour would, according to many figures, have only about an equal chance for survival.

In conclusion, there do appear to be corridors which could be traversed in orbital flight, since, according to present data, there seems to be an envelope above the sensible drag of the atmosphere, above about 140 miles, yet under the serious concentrations of Van Allen-type radiation beginning at about 400 miles. Man probably could travel in this area, providing his orbit approached an ideal circular configuration. From the standpoint of escape into the outer reaches of space, the corridor of minimum Van Allen-type radiation is almost exactly that of the maximum concentration of primary cosmic radiation. Whether or not such orbits could be fitted in to our present patterns set up by propellant energies, "g" tolerances, and celestial mechanics, is an outstanding question, as is the problem of shielding within allowable weight restrictions. Those of us interested in space travel, however, are noted for optimism.

BACTERIAL PRODUCTS CAN SUPPRESS MULTIPLICATION OF VIRUS IN TISSUE CULTURES.—We have observed on numerous occasions a suppression of virus production in tissue cultures treated with bacterial filtrates. In these instances the filtrates have produced no visible change in the cultures and the cytopathogenic effects seen after infection with virus have not differed from those observed in control cultures. We do not therefore think that the inhibitory effect which we have observed is due to a crude "toxic" effect on the cells of the monolayers. It was shown experimentally that the filtrates tested did not have a direct inactivating effect on the free virus of the tissue culture fluids. Furthermore, in none of the experiments could we find evidence that the attachment of virus to the cells was prevented. It would appear, therefore, that the endotoxin filtrates affect virus multiplication within the cells. Sterile crude filtrates of the normal bacterial flora of 2 out of 3 persons tested suppressed the growth of poliovirus in monkey kidney tissue cultures. The active principle was found to be present in 3 out of 4 strains of Bact. coli isolated from one of these persons. Partly purified endotoxin of Salm. typhymurium produced the same effect to a much higher degree.—M. Likar, E. O. Bartley, and D. C. Wilson, Observations on the Interaction of Poliovirus and Host Cells in Vitro: III. The Effect of Some Bacterial Metabolites and Endotoxins, *The British Journal of Experimental Pathology,* August, 1959.

PSYCHOPHYSIOLOGY OF HYPNOSIS

Louis J. West, M.D., Oklahoma City

The theory of hypnosis here formulated postulates certain psychophysiological mechanisms, especially the ascending reticular activating system, through which interpersonal and intrapersonal forces operate to achieve and maintain the hypnotic state. From this theory it can be predicted that certain drugs, such as the phenothiazine derivatives, will render the chronically anxious patient more accessible to hypnosis whereas certain others, such as phenobarbital, will not. These predictions are in accord with the author's experience.

There are many reasons for assuming that the hypnotic state is essentially a controlled dissociative reaction.[1] However, this view requires a broader model of the psychophysiology underlying the process of dissociation than has hitherto been formulated. A stereotyped presentation appears in many standard textbooks, with definitions that are virtually identical with Janet's original ones, giving only a limited concept of the mechanisms involved in dissociation and their role in normal as well as abnormal psychological functions.

The four classic dissociative reactions are fugue, amnesia, somnambulism, and multiple personality. However, the dissociation from awareness of sensory phenomena (seen in conversion hysteria or in hypnotic anesthesia), the dissociated experience of sensations or feelings without appropriate external or internal stimuli (as in hallucinations, *déjà vu*, or feelings of unreality), and certain episodes of unusual behavior seemingly beyond conscious control are frequently accepted within the framework of modern dynamic psychopathology as dissociative phenomena.

In the past 10 years an increasing fund of data concerning the physiology of awareness has made it possible for us to see the clinical dissociative reactions as pathological exercises of certain normal brain mechanisms. Whatever one may choose to call these mechanisms (perhaps "parassociative" would be an appropriate term), they subserve the functions of scanning and screening information and regulating the sphere of awareness moment by moment. Only a minute portion of total available information—from the external environment, from within the body, and from the brain's own enormous stores—can be held in awareness at any given time. Concentration, reality-testing, and simple survival require the exercise of scanning and screening mechanisms to keep the searchlight of awareness focused on selected areas of psychic content and to keep everything else out of awareness.

Theoretical Considerations

Weitzenhoffer[2] recently defined hypnosis in terms of a "dissociation of awareness from the majority of sensory and even strictly neural events that are taking place." This definition implies an appreciation of the combined functions of focus and exclusion, or of a balance between excitation and inhibition, which is shared by the psychoanalytic theories[3] of hypnosis on the one hand and the Pavlovian[4] on the other. But such a "dissociation of awareness" characterizes not only hypnosis but all of the classically defined dissociative reactions. It also covers the more recently defined clinical dissociative phenomena as well as dreams, hypnagogic states, sleep paralysis, "highway hypnosis," trances and ecstasies in mystical and religious rites, "fascination" or "fixation" in flyers, daydreaming, and many other mental phenomena, including the exercise of normal concentration at all levels of intensity. The "majority of sensory and neural events" are probably always excluded from consciousness at any given time in a normal person.

Apparently a sufficient amount and variety of sensory input is required to maintain the exercise of the parassociative mechanisms in relation to current external reality. In prolonged monotony, or in artificially produced sensory isolation or sensory deprivation such as described by Hebb,[5] Lilly,[6] Shurley,[7] and others, the diminished input of sensory information in the presence of continued alertness permits an increasing awareness of the brain's previously recorded perceptions. These, being released into consciousness and woven into scenes or invested as symbols by psychodynamic forces, are then perceived as images or hallucinations.[8] During those periods of sleeping in which cortical arousal increases without significant increase in appreciation of environmental stimuli, a basically similar phenomenon occurs and dreaming takes place, as Dement and Kleitman[9] have shown.

Elsewhere a conceptual model has been formulated to account for dreaming and all hallucinatory experience in terms of released perceptions.[8] This

model includes a consideration of the role of fatigue or input-overload of the sensory systems, as in sleep-deprivation; the blocking or poisoning of the sensory systems by drugs such as *d*-lysergic acid diethylamide (LSD-25), which distort perception and also stimulate the diencephalic centers regulating arousal; the differential chemical effect on sensory and arousal systems in the person going into and coming out of anesthesia; and the deliberate or unconscious withdrawal from or narrowing of focus on the sensory environment in the schizophrenic, the mystic, the hysteric, the hypnotic subject, the pilot concentrating on his altimeter, or the father of a family concentrating on his newspaper.

Role of the Reticular Formation

Does the brain have a definable system to permit an infinitely variable integration of incoming information on the one hand and awareness on the other? A structural basis for such a function may now be postulated. In 1942 Morison and Dempsey[10] described a nonspecific thalamocortical projection system. This was followed in 1949 by the classic paper of Moruzzi and Magoun,[11] defining some of the functions of the ascending reticular activating system. At about the same time Jasper[12] noted the relationship of the thalamic reticular formation to the previously described thalamocortical projection system. Further discussions by Magoun,[13] Lindsley,[14] MacLean,[15] and others clarified many of the regulating functions subserved by the ascending reticular activating system. It soon became apparent that the integrating effects of this extraordinary network involve not only sensory information and arousal or alertness but also emotions, memories, and transactions between neocortical and paleocortical structures.

At the present time it seems fair to say that the ascending reticular activating system integrates the relationship between sensory information and awareness. Together with the diffuse thalamocortical projection system it permits both general arousal and attention to discrete stimuli. Feedback systems from the cortex, both stimulatory and inhibitory, have recently been described. The differential functioning that is now known to be possible within the total activity of the reticular formation, whereby stimulation, inhibition, arousal, and depression can be reciprocally exercised simultaneously in different areas, makes it possible to comprehend the anatomic basis for the screening and scanning functions which must exist.

In the 10 years that have elapsed since the first paper on the ascending reticular activating system came from Magoun's laboratory, sufficient information has been compiled about its activities and interrelationships to appreciate how it subserves the reality-testing functions of the ego. When there occurs a marked narrowing of focus of awareness on a particular aspect of reality, to the exclusion of much of the rest (as in the initiation of the hypnotic trance), then sensory data (verbal suggestions) taken in through an open channel (rapport) become effective because they are not subjected to ordinary reality-testing.

The reticular activating system will maintain arousal while inhibiting appreciation of a considerable degree of reality under two circumstances that can be demonstrated in the laboratory. The first circumstance is one in which attention is fixed by a narrow range of stimuli, monotonously presented. The relatively gradual but definitely progressive decrease in reactivity to other stimuli under these circumstances can be demonstrated behaviorally in man as well as in lower animals under certain conditions. The other circumstance under which the reticular activating system functions in this manner is in the presence of an input-overload. When arousal is already high (because of strong emotion or vigorous stimulation, or both, simultaneously via several sensory modalities) feedback mechanisms cause the functional nonacceptance of nearly all additional incoming information, regardless of its significance under ordinary circumstances of adaptation.

Clinical Correlations

The experienced hypnotist will recognize these two psychophysiological situations as the most probable concomitants for the two characteristic clinical situations in which hypnosis may be easily induced: the gentle, monotonous, object-focused laboratory technique on the one hand and the emotion-laden, high stimulus–input stage technique on the other. The first is near the hypnagogic point with a low level of arousal but an even lower level of effective input; the second is near the point of spontaneous dissociative phenomena under conditions of great arousal and impaired effective input, due to input-overload's figuratively "jamming the circuits."

Between these two extremes, at the point of maximum conscious influence on reticular-formation activity, deliberate exclusion of external stimuli may be achieved through intense concentration. It is probably in this way that the trained subject quickly enters the trance state on receiving his previously defined signal from the hypnotist. Kubie and Margolin[3] formulated a theory of the psychodynamics of the relationship between hypnotist and subject that permits the trance to be induced. The theory here formulated postulates the psychophysiological mechanisms through which interpersonal and intrapersonal forces operate to achieve and maintain the hypnotic state.

Since the normally operative parassociative and integrative functions subserved by the ascending reticular activating system are fundamentally involved in hypnosis, the continuity of the hypnotic state with normal states of concentration is easily seen. This can blend into hypnagogic reverie on one extreme and into agitated arousal with spontaneous dissociations on the other. Thus it might be expected that older reports of normal waking electroencephalographic tracings of patients in the hypnotic state might be modified by the discovery of both hyperarousal patterns and drowsy patterns bordering on genuine sleep existing in patients under certain conditions of hypnosis. Recent observations indicate that this is indeed the case. The psychophysiological theory expounded here, wherein the state of arousal is seen to be less important than the relationship between arousal and effective sensory input, permits us to comprehend the maintenance of hypnotic rapport under a variety of electroencephalographic conditions. It also permits us to understand differences in autonomic responses to stimuli as well as in subjective appreciation of them.[16]

Hypnosis and Drugs

Similarly, the frame of reference provided by this theory permits a better understanding of the relationship between the actions of various drugs and the induction and maintenance of the hypnotic trance. No drug can be evaluated for its adjunctive value in the induction of hypnosis without first considering the [illegible] state of the subject at the tim[illegible]eing just right for the induction of hypnosis, will enter the trance easily, without the use of drugs. A drug administered under these circumstances (e. g., thiopental [Pentothal] sodium given intravenously to a soldier with an acute dissociative reaction in combat) may appear to be quite effective, when in actuality hypnosis is occurring, because of the psychological effect of the injection on both subject and operator, and perhaps in spite of the neuropharmacological effect of the medicament.

The patient who is chronically anxious may be rendered distinctly more accessible to hypnosis by the use of a drug which decreases central autonomic reactivity while maintaining a good cortical arousal pattern. In my experience this is borne out by the fact that phenothiazine derivatives can be helpful in such cases, whereas phenobarbital (which depresses arousal) usually is not. On the other hand, in a patient in whom tension is prominent, with manifestations chiefly in the musculoskeletal system, a barbiturate or meprobamate preparation may be helpful. Although such stimulants as amphetamine and methylphenidate have seemed to make hypnosis more difficult to induce in certain patients, they may help, when combined with barbiturates, to ease the induction of hypnosis in tense, depressed persons.

If hypnosis is seen as a controlled dissociated state, or a special state of concentration maintained through the parassociative mechanisms mediated by the ascending reticular activating system, it might be expected that drugs which cause spontaneous, pathological, dissociative phenomena to appear would at the same time render difficult or impossible the maintenance of a hypnotic trance. This has been true in my experience with the effects of LSD-25, even though the subject under its influence may be more suggestible. On the other hand, protective or reassuring hypnotic suggestions made prior to the administration of LSD-25 appear to help the subject to withstand the disorganizing and frightening effects of the drug.

Summary

Psychophysiologically, the hypnotic trance may be defined as a controlled dissociated state. This state of altered awareness is maintained through "parassociative" mechanisms mediated by the ascending reticular activating system. These mechanisms probably involve the thalamocortical projection system, corticofugal systems both excitatory and inhibitory, and other integrated regulatory systems known to function in connection with the ascending reticular activating system. When the subject is in the hypnotic state, alertness is maintained relative to the inhibition or exclusion from awareness of considerable amounts of incoming information that would ordinarily be consciously perceived in the process of reality-testing. Under these circumstances the information inserted into the restricted area of the subject's awareness by the hypnotist, through his suggestions, is accepted as reality to a greater or lesser extent, depending on the subject's dissociation of other information from awareness, moment by moment. Recently observed bioelectric variations during the hypnotic state, as well as differing reactions of hypnotic subjects to drugs under various circumstances, are compatible with this theory, which is formulated primarily to stimulate further discussion and research.

TECHNIQUES OF HYPNOSIS

William S. Kroger, M.D., Chicago

Methods for inducing formal hypnosis are classified as direct or authoritarian, indirect or permissive, and mechanical. Preliminary tests determine a patient's susceptibility to suggestion and help to decide which method to use. The subject must understand that hypnosis is not sleep and that he will be more, not less, acutely aware. He must understand that he himself induces the hypnotic state and that the operator is only acting as a guide. This "patient-centered hypnosis" differs greatly from the outmoded and dramatic authoritarian methods of the 19th century. Methods of induction are readily learned; the real problem is what to do after that.

Nearly all modern techniques for inducing hypnosis depend on a favorable "mental set" produced in the subject. This attitudinal change is brought about by misdirection, belief, confidence, and expectation—all catalyzed by the imagination. Therefore, the elicited sensory and motor responses are phenomena which are based on the subject's conviction. Conviction of hypnosis leads to hypnosis. Actually, no one really hypnotizes another person. It is, indeed, a wise hypnotist who knows who is hypnotizing whom.

Hypnosis is more readily induced if the patient knows what to expect, especially if all popular misconceptions are removed a priori. If misdirection (a ritualistic or even a formal hypnotic induction procedure) is employed, susceptibility to suggestion is also enhanced. Any technique which obscures the fact that direct suggestion is being used is misdirection. The essential ingredients for hypnosis are present whenever a highly motivated person receives prestige suggestions from a person in an authoritarian position.

Methods of Induction

In general, even though variants are used, most methods for inducing formal hypnosis belong to one of the following groups: the direct or authoritarian, the indirect or permissive, and the mechanical techniques. All utilize ideomotor and "ideosensory" conditioning. The latter term refers to the development of sensory images or percepts. These are meaningful impressions which may be evidenced by positive or negative hallucinations. Such perceptual alterations can be produced by tactile, olfactory, visual, gustatory, or auditory stimuli. For instance, "seeing" the image of one's beloved in the flames of a fireplace is a positive visual ideosensory hallucination.

The "disappearance" of the audience to a deeply hypnotized subject is an example of a negative ideosensory hallucination. Ideomotor activity refers to unconsciously produced muscular actions; an excellent example is the "back-seat driver" who "steers" the swerving car by bending in the opposite direction.

Direct.—All methods of direct induction depend on eye-fixation, with resultant fatigue and relaxation of various muscle groups, first small and then large. Utilization of ideomotor and ideosensory

---

Read in the Symposium on Hypnosis before the Joint Meeting of the Section on Anesthesiology and the Section on Nervous and Mental Diseases at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 11, 1959.

activities is as follows: "If you really wish to become more and more relaxed, just stare at the ceiling and you will notice that your eyelids are getting very, very heavy (ideosensory), indicating that you wish to close your eyes." Subjects are not aware that the eyelids get heavy and blink because of physiological factors; they attribute the tired, drowsy effect to the hypnotic technique—another form of misdirection.

Other direct techniques begin with eye closure. The suggested ideosensory and ideomotor activities motivate the subject and increase the depth of hypnosis. A rapid and direct method based on ideomotor and ideosensory conditioning is called the coin technique. In this technique the subject's thumb is used as a fixation point. Instructions are given that, at the count of three, two things will happen: the eyes will close tightly and at the same time the fingers, which tightly clasp a coin, will open and allow the coin to drop. The sound of the coin hitting the floor will be a signal that the eyes are closed tightly. At the moment of eye closure the outstretched arm is lightly stroked to produce limb catalepsy or rigidity, a sign that a medium stage of hypnosis has been reached. To insure success, instructions to close eyes and simultaneously allow the coin to drop can be repeated several times.

Indirect.—Methods of indirect induction make use of visual sensory imagery, as in the blackboard or escalator techniques. Sensory imagery techniques, in which a television or motion picture screen is imagined in the mind's eye and then utilized for hallucinated material, are best for children because of their vivid imaginations.

Visual Imagery Technique: The patient is told, "Close you eyes and relax comfortably. That's fine. Relax all over. If you will, please imagine the most comfortable chair in the world. Do you see it? (Pause and obtain response.) Soon it will be occupied by another person. Describe that person to me. (Wait for response.) Would you be willing to help me teach 'X' (person described by subject) how to go into hypnosis?" Obtain an affirmative response. Then the verbalization for a slow involuntary lifting or levitation procedure is used. The patient is interrogated about the responses that the hallucinated "subject" makes and is asked to encourage the subject to "see" the other's responses. The patient's own motor activity simulates the subject's. As he himself responds to those suggestions ostensibly made to the hallucinated subject, the shift is gradually made from the subject to the patient, until hypnosis has been accomplished.

Included in indirect methods are disguised or hidden techniques which achieve relaxation through the misdirection of taking the subject's blood pressure. As cuff pressure is released, the operator remarks, "As your blood pressure drops, you become more and more relaxed." Indirect hypnotic techniques require more active participation of the subject; in the direct approach the operator or hypnotherapist does all the work.

Mechanical.—Mechanical techniques employ repetitive visual, auditory, or tactile stimuli produced by any one of a number of devices. These consist of a metronome, whirling disks, and electronic instruments which rhythmically emit flashes with or without verbalization techniques. It has been postulated that photic "driving" of the alpha wave might induce a drowsy or dissociated state of greater receptivity to suggestions.[1] Kroger and Schneider[2] recently described an instrument called the brain wave synchronizer, an electronic device which, when used with a standard verbalization technique, induces various levels of hypnosis, possibly by photic stimulation of the brain waves. The instrument can be used alone or combined with a tape recording of the therapist's induction and dehypnotization techniques. This apparatus has helped to induce light to deep hypnosis in a high percentage of subjects. Naturally, a response is more readily effected if a favorable "mental set" is created. To some extent the expectant attitude resulting from the structured situation enhances the effectiveness of the instrument. However, about 30% of subjects who did not receive an explanation of hypnosis, nor have any knowledge that the brain wave synchronizer could induce the hypnotic state, were hypnotized to the degrees mentioned. The apparatus can deepen the hypnotic level and also speed up induction, often a time-consuming procedure, especially in refractory persons. An important advantage which eliminates apprehension is that no physical contact with the patient is required.

Conditions for Successful Hypnosis

The unsophisticated operator can determine a person's susceptibility to suggestion by various preliminary tests. For this purpose the hand clasp and postural sway tests are rapid and simple procedures. In the first, suggestions are given that the hands are tightly locked and cannot be parted. If there is difficulty or a time lag in separating the clasped fingers, this usually indicates ready hypnotizability. In the second, if the subject sways backward toward the operator in response to such suggestions, positive susceptibility is present, whereas even a slight forward swaying is presumptive evidence of resistance.

Generally, intelligent persons who can concentrate and who are highly motivated make the best hypnotic subjects; exhibitionists are, with the exception of those who use resistance as an attention-getting device, easy to hypnotize. Imbeciles, morons, and psychotics are difficult, if not impossible, to hypnotize. Those who are extremely analytical of the operator's suggestion are not good subjects. For this reason, it is necessary to employ some type of misdirection to get the subject's attention diverted to other percepts. Psychoneurotics who need hypnotherapy are more difficult to hypnotize than are those who volunteer for entertainment hypnosis; the latter have "nothing to lose" nor have they any symptoms to give up. Neurotics seldom relinquish symptoms which fulfill a definite need in their emotional make-up. Although the optimum age of a subject for hypnosis is over 8 years, it can be induced in persons from about the age of 6 years to old age.

If the subject's attention is concentrated on the suggestions of the operator, then an appropriate response is more readily obtained. Since hypnosis is a subjective and naturalistic phenomenon, it is imperative to have the subject's confidence. Conviction of hypnosis leads to hypnosis. An ungarbled message is generally received whenever a pipeline of communication is established between two persons. Attention is focused if "noise" or "static" on the "circuits" is eliminated. The factors which determine conviction depend on the attitude of the subject, the prestige of the operator, and the strength of the interpersonal relationship.

A healthy rapport is necessary for establishment of hypnosis. Naturally, the rapport is influenced by the emotional resistances of the subject as well as by the feelings and actions of the operator. These transactional processes involve many interrelated and overlapping forces within the total field of human behavior which are beyond the scope of this discussion.

The decision to employ permissive or authoritarian techniques depends on the personality of subject and operator. All therapists must be capable of switching from one approach to another, even during the same induction. Generally, passive persons respond to authoritarian techniques while subjects with dominant personalities do better when a more permissive approach is used. Persons insusceptible to either of the above methods frequently may be hypnotized by mechanical means.

Regardless of the method used, every good operator must be aware of such fundamental principles of hypnotic induction as never "losing face," promising results which may not be fulfilled, nor offering premature challenges. Subjects who are unable to respond to the suggestions of the therapist must be "given a way out." Suggestions for the subject's benefit and in accord with his wishes are more likely to be acted on because a critical attitude is not mobilized. Successful hypnotic response will be proportionate to the subject's cooperation. Motivation for hypnotic induction can be enhanced if the hypnotherapist emphasizes that the simple, elementary suggestions must be sequentially followed in order for the subject to benefit from the posthypnotic therapeutic suggestions. This places the onus or responsibility for entering hypnosis on the subject. Since everyone has a varying capacity to respond to verbal, nonverbal, intraverbal (intonation of voice), and extraverbal (implied meaning of words) suggestions, nearly all persons can achieve some degree of hypnosis.

The misconceptions which must be removed are feelings on the part of the patient that he will become unconscious or asleep, surrender his will because of "weak-mindedness," fail to "wake up," become comatose, or babble and reveal shameful secrets, as one might under anesthesia. Subjects should be informed that they cannot be made to violate their moral codes and that suggestions contrary to their wishes usually will not be followed.

Physician hypnotherapists should never use posthypnotic suggestions for their own ego-aggrandizement. The stage hypnotist or unsophisticated operator usually "plays God" with hypnosis because he thinks he has a special kind of "power." Actually, the subjects of the stage hypnotist are hypnotized even before they volunteer, because of their expectant attitudes.

The most common misconception is that hypnosis is sleep. Many deeply hypnotized subjects state, "Doctor, I am sure I was not hypnotized, I heard everything you said." Therefore, all subjects must be told that they will be more, not less, acutely aware. Actually, the purpose of the hypnotic state is to produce a hyperacuity of all the senses so that more attention is directed to the operator's words; thus, sensory and motor responses are carried out with literalness or "pinpoint" precision. Hypnotic response is further facilitated by making the subject comfortable and eliminating all distracting influences; a soundproof room free from interruptions helps to promote relaxation.

Confidence is essential, since all subjects, on the basis of subliminal cues, pick up any insecurities and hesitancies in the operator's verbal, nonverbal, intraverbal, and extraverbal suggestions; therefore, he should approach every induction with full expectation of success. Subjects readily recognize the experienced operator, and conviction of success based on his positive approach enhances cooperation and facilitates induction. There can be no modicum of success in the absence of conviction and cooperation.

Properly motivating the subject by pointing out how positive, constructive, healthful conditioning can neutralize negative, destructive, and harmful influences often eliminates conscious resistance to hypnosis. Further resistance to acceptance of suggestions results whenever, as mentioned, critical attitudes are mobilized. Therefore, suggestions must be fully in accord with the patient's needs. Patient negativism generally is due to faulty use of suggestion and improper motivation. Here, too, the inexperience of the operator affects the subject's susceptibility to suggestion. Hence, clarity and simplicity in the giving of suggestions enable the subject's imagination to respond according to the wishes of the operator. To minimize failure, subjects should also be instructed that the harder they deliberately will themselves to follow suggestions, the more difficult it will be to do so. It is axiomatic that, whenever the will and the imagination come into conflict, the imagination wins out. Hence, successful induction of hypnosis requires the subject's imagination to be involved in as many ideosensory and ideomotor responses as possible. This is readily attained by having the subject believe or imagine that his body is becoming heavy.

Monotonous repetitive stressing of such key words as "heavy" and "relaxed" narrows the field of awareness so that the subject's ability to concentrate is increased. Building up ideosensory and ideomotor responses, first by simple suggestions and then by more complicated ones, limits voluntary movement and is conducive to hypnotic relaxation. For instance, "With every breath (ideomotor) you take, and every number you count backwards (ideosensory), you will become more and more relaxed." I never use the word "sleep" in my induction technique unless the term is qualified by saying, "You will become more and more relaxed and sink into a sleep-like state, yet you will hear everything I say." Although many hypnotherapists use the term "sleep," confusion is created unless this phrase is qualified. Reinforcing a psychological suggestion (ideosensory) by a physiological effect, like lightly stroking a limb (ideomotor), further facilitates the subject's acceptance of suggestions. These suggestions must be given slowly, and sufficient time must be allowed for their assimilation.

Problems with the Hypnotic Subject

Negative conditioning, such as telling the subject he is difficult to hypnotize, is harmful. Rather, positive conditioning—that he did very well for the first time and that he will do better the next time—facilitates future inductions. Fearful subjects should never be traumatized by too early testing for anesthesia. One must be certain that the phenomenon has occurred. Fear over failure to enter hypnosis and anxiety can be allayed by a confident, sympathetic, and reassuring approach rather than a condemnatory one. Blaming the patient for his inability to enter hypnosis only creates further resistance.

Many resistant persons have a skeptical and analytic attitude. In some, overcooperation is a defense against being hypnotized. Others are merely curious or are unable to concentrate because of tensions associated with being hypnotized. All these factors decrease rapport. Apprehensive persons may also show such other indications of conflict as excessive giggling or laughing, sweating, and trembling, all of which are indicative of other deep-seated tensions and fears; weeping and crying are indicative of profound anxiety. Induction should not be continued in such emotionally disturbed persons because chagrin, a sense of failure, and other depressive reactions can readily be produced, especially in those with prepsychotic personalities. Unless the operator is experienced, he should terminate the induction. Although induction of hypnosis depends on the strength of the interpersonal relationship, it is an intensely intrapersonal problem for the subject.

The deep or somnambulistic hypnotic state is readily recognized; it is characterized by immobility of the facial features; staring eyes; loss of startle reflex; slow, slurring speech; catalepsy of large muscle groups; economy of motion; and a time lag or gap between the giving of a suggestion and the response to it. A medium depth is indicated by limb catalepsy, ease of lid closure, inability to open the eyes after closure, trembling and twitching of eyelids, and a more moderate degree of neuromuscular relaxation. Since the perceptual fields are narrowed to all sensory input, intense absorption in physiological activities occurs.

The skillful operator closely observes his subject's responses in order to use every voluntary or involuntary manifestation to reinforce the subject's expectation and belief that hypnosis will occur. For instance, if the subject's eyelids tremble involuntarily during the initial phase of induction, the operator can remark, "The trembling of your lids is a good sign that you are becoming more and more relaxed." If the patient voluntarily swallows one can say, "You just swallowed, that's good; it shows you are relaxing." Such points should always be made on a logical basis and bear the stamp of validity to be accepted. Also, one must avoid giving the impression that each and every suggestion will be acted on. If necessary, whenever a suggestion is not followed, the experienced operator changes to another so that the patient is unaware that either he or the operator has temporarily failed.

I strongly emphasize that better results will be obtained if the sequence of the suggestions is not broken. Before inducing hypnosis, it is a good idea to tell the subject what you are going to do, what he is to expect, and what you expect of him. Let him understand that you do not really induce the hypnotic state, that he does, and that you are only acting as a guide. If he follows elementary instructions, he will follow others and enter deeper states of hypnosis at his own pace and desire. When possible, it is generally helpful to have a new patient observe an induction procedure in a well-conditioned subject—a few minutes of observation is worth hours of discussion. Through emotional identification with patients who successfully enter hypnosis, the subject now understands what to expect and this helps to overcome resistances.

Techniques for deepening the hypnotic state are achieved by establishing a definite goal for each step of the induction procedure. "As you raise your arm higher and higher, with every upward motion of your arm you will become more and more relaxed." Linking these suggestions with physiological processes is helpful. For example, "With each beat of your heart you will become more and more relaxed." Vogt's fractionation technique[3] is an excellent one for deepening hypnosis. In this technique the subject is dehypnotized and asked what sensations of relaxation or drowsiness he had. These are then "fed back" to the subject, with suggestions that he will become more and more relaxed with each opening and closure of eyes.

Autohypnosis is often called autoconditioning or autogenic training. It is best produced by a progressive relaxation technique, which can be taught while the subject is under hypnosis. The subject is given specific instructions for inducing self-hypnosis as well as for dehypnotization. This is "patient-centered hypnosis" and differs greatly from the outmoded and dramatic authoritarian methods of the 19th century.

Autohypnosis, together with production of glove anesthesia, is ideal for obstetric hypnoanesthesia.[4] The suggested "anesthesia" of the palms is transferred to the abdomen during labor to mitigate the pain of the uterine contractions. Autohypnosis and glove anesthesia are particularly valuable during group training sessions, in which the "emotional contagion," inherent competitiveness, identification with successful subjects who readily develop autohypnosis, and desire to please the therapist all facilitate hypnosis.

For surgery a rehearsal or "dry run" under hypnosis raises the pain threshold by teaching the subject to know what to expect. Such experiential conditioning under hypnosis automatically raises the pain threshold.[5] This method is called Schultz's autogenic training.[6] When terminating hypnosis in those who have entered either light, medium, or deep states, it is imperative to remove all suggestions except those that are to be used posthypnotically.

The dangers resulting from faulty techniques are minimal. In the trained physician's hands, there are really no dangers from the use of hypnosis per se, but harm may result from what is said to a hypnotized person or from failure to understand the responsible psychodynamics. The same dangers occur (when physicians untrained in psychiatry treat severely disturbed patients) at the nonhypnotic level. Janet once said that the only danger of hypnosis was that it was not dangerous enough. Nevertheless, hypnosis should be employed only by doctors for specific purposes in selected patients. Physicians should also realize their limitations and not exceed their psychotherapeutic orientation or ability.

Summary and Conclusions

Induction of hypnosis should not be attempted until all misconceptions have been removed and the patient is comfortable and free from distracting stimuli. Thereafter, a confident and positive approach by the therapist will enhance his prestige and eliminate the conscious and unconscious resistances of some patients. The therapist must be alert to those signs which indicate whether authoritarian or permissive procedures are necessary. Sometimes a combination must be used, since rapport fluctuates.

All induction techniques employ ideomotor and "ideosensory" activities which produce a favorable "mental set" or attitude based on belief, confidence, and expectation, catalyzed by the subject's imagination; hypnosis occurs as the result of this reaction. All hypnotic techniques should also limit sensory input and narrow conscious awareness to the suggestions of the therapist. These suggestions must be repetitive, stress key words, and be delivered in a monotonous manner. Hypnosis is cumulative, and once initial suggestions have been carried out further suggestions will alter sensory and motor capacities to produce appropriate responses. To obtain responses the therapist must be conversant with the types of personality of patients who will react to each technique. He must also employ a technique which uses the highest potential of his own personality. Autohypnosis, which enables the patient to induce and terminate the hypnotic state, increases motivation, and this "patient-oriented hypnosis" differs greatly from the dramatic methods of the 19th century wherein the therapist "played God." Deepening procedures make use of the patient's experiential background; Vogt's[3] fractionation technique and Schultz's[6] autogenic training are valuable adjuncts.

In surgery, autogenic training and rehearsal raise the pain threshold. The "dry run" removes fear and tension. Group hypnotherapy is always the preferred method because of "emotional contagion." Those who readily enter the hypnotic state stimulate those less suggestible to a cooperative attitude and identification. Equally important, the time factor is obviated by inducing the hypnotic state in many patients simultaneously. An electronic instrument, called the brain wave synchronizer, now aids the operator's verbalizations in these group sessions by inducing varying degrees of hypnosis, probably by photic "driving" of the alpha waves.

Hypnotic induction can be as readily learned as the technique for making an abdominal incision. The real problem is what to do with the "scalpel" after that. Induction is just the first step and is, in reality, produced by the subject as a result of the conviction that hypnosis will occur. Much clinical experience is needed to become proficient, and only through experience can the necessary confidence be gained.

"HYPNOSIS," ANALGESIA, AND THE PLACEBO EFFECT

Theodore X. Barber, Ph.D., Cambridge, Mass.

Pain is a composite phenomenon, and not all aspects of pain are abolished by hypnosis. Subjects who report that they experience hypnotic analgesia or hypnotic hallucination are able to carry out a similar type of behavior without a hypnotic induction procedure. It has not been experimentally demonstrated that hypnotic procedures offer more satisfactory relief from pain than do placebos. The placebo effect has been reported to give satisfactory relief from severe postoperative wound pain in about 30% of patients; estimates as to the number of persons who manifest or experience such phenomena as hypnotically induced analgesia, age-regression, hallucination, and amnesia range from 5 to 25% of the population. Narcotics and hypnotic procedures do not necessarily affect the sensation of pain per se. By mitigating anxiety and inducing a bemused state they alleviate discomfort and appear to suppress the pain sensation.

Within recent years hypnotic procedures have proved successful in minimizing the pain associated with childbirth, spinal cord injuries, terminal cancer, fatal burns, mastoplasty, and thyroidectomy.[1] Although hypnotic techniques are gradually finding a useful place in the anesthesiologist's armamentarium (especially in cases in which chemical analgesics are contraindicated), the means by which "mere words" spoken by one person to another are able to exert an analgesic effect has been left unexplained or has been discussed in terms of concepts which are themselves in need of explanation such as "the power of suggestion," "the unconscious," or "the trance state." Nevertheless, sufficient data have accumulated to delineate two factors which are responsible for the effectiveness of hypnotic methods in minimizing pain. One of these factors is similar to a placebo effect; the other resembles the mode of action of morphine. Before analyzing these factors, however, a brief discussion is necessary to clarify the concept of hypnotic "analgesia."

The Semantics of Hypnotic "Analgesia"

The term "pain" carries a number of connotations which require careful differentiation. The normal response to nociceptive stimulation includes at least three interrelated components: (1) the awareness of pain as a sensation, (2) discomfort or suffering, and (3) one or more systemic physiological alterations, such as an increase or decrease in blood pressure.[1b] With selected patients, hypnotic procedures can minimize discomfort and suffering and can minimize the physiological alterations which normally follow nociceptive stimulation, without necessarily affecting pain as a sensation. Dorcus and Kirkner,[2] for example, reported that hypnotic procedures alleviate suffering in patients with spinal cord injury not by suppressing "the primary pain-arousing mechanism" but by minimizing "factors that tend

to focus the individual's attention on the pain." My recent experiments and earlier experiments by others [1b] have demonstrated that, when the noxious stimuli are not too severe, some good hypnotic subjects do not show discomfort (by wincing, withdrawal, tremor, or restlessness) and do not show significant alterations in blood pressure, pulse rate, or respiration; however, careful questioning of these subjects reveals that the pain sensation is actually present but appears to be minimized or eliminated because the subjects are able to stop attending to, to concentrate away from, and to inhibit all thoughts about the noxious stimulation and the concomitant painful sensation.

The Good Hypnotic Subject

Although the amount of chemical anesthetic administered can be significantly reduced with most surgical patients by the adjunctive use of hypnotic procedures, persons who are able to undergo major or minor surgery with hypnotic procedures alone are a minority of the population, at least in Western nations. In the experimental laboratory, I found that hypnotic suggestions are effective in minimizing the discomfort associated with such noxious stimulation as Lewis' muscle ischemia tests [2a] in about 15% of a sample of the student population.[1b] Along similar lines, Winkelstein [3] reported that when hypnotic procedures are used without other analgesic agents 7% of 200 obstetric patients were able to give birth without noticeable discomfort or suffering. Other estimates as to the relative number of "somnambulists," i. e., persons who are able to experience such phenomena as hypnotically induced analgesia, age-regression, hallucination, and amnesia, range from 5 to 25% of the population.[4]

These persons possess distinctive characteristics and abilities. Young [5] noted that all of his good hypnotic subjects showed one or more of the following characteristics long before they were ever "hypnotized": "deep abstraction, reverie amounting almost to ecstasy, putting oneself to sleep at will, actually hypnotizing one's self." Similarly, in a series of investigations [6] I found that subjects who are able to experience such phenomena as hypnotic analgesia or hypnotic hallucination are also able to carry out a similar type of behavior without a hypnotic induction procedure. For example, these subjects typically report that they do not require a local anesthetic for dental work; prior to participating in hypnotic experiments, they had discovered that by thinking about something pleasant and inhibiting all thoughts concerning the dental situation they could undergo various dental procedures without discomfort.[6b] Apparently these persons are able to carry out the essential behavior involved in "hypnosis"—are able to become relatively inattentive and unresponsive to selected stimuli—with or without a formal hypnotic procedure.

However, to undergo major surgery or to be relieved of severe pain by hypnotic methods, the patient must also believe that "hypnosis" can relieve his pain and he must be set to accept his physician-hypnotist's words as valid descriptions of reality. Kroger [7] concluded from extensive clinical experience with hypnotic techniques that "when one wishes to perform major surgery under hypnoanesthesia . . . it is very important to get the patient to believe in the actuality of the trance state." Somewhat along similar lines, Leuba [8] concluded from his experimental work that "there must be a concentration on the ideas presented by the hypnotist and with a minimum of counter or critical thoughts; and a belief that what the hypnotist says will happen, can actually happen, and will happen. In other words there must be a set or attitude to accept the hypnotist's statements completely and uncritically." Recent experiments [9] indicate that these propositions are valid: "Somnambulistic" subjects do not carry out the more difficult hypnotic behaviors (such as hypnotic deafness or blindness, negative hallucinations, or analgesia to severe nociceptive stimuli) when the hypnotist simply gives them the appropriate suggestions. Something more is required: The hypnotist must manipulate his words and the situation in such a way as to lead the subject to believe that the suggestions are literally true statements. Clinical reports emphasize an additional factor which is closely related to this: The patient must have confidence in his physician-hypnotist. After use of hypnotic methods with 200 consecutive obstetric patients, Winkelstein [3] concluded that "the mental attitude of the patient, the patient-obstetrician rapport, and the confidence of the patient in the procedure as well as in the accoucheur, seemed to be as important factors as was the hypnosuggestion itself." Butler [4a] also noted that a close interpersonal relationship between physician and patient is necessary in treating the patient suffering from terminal cancer by hypnotic methods. He reported that when hypnotic procedures were abruptly terminated the patients all showed a dramatic return of the original suffering; however, when hypnotic methods were discontinued but the patients received the same amount of personal attention from the physician, discomfort and suffering were minimized for a few days to the same extent as during the hypnotic sessions. The author emphasized that when the physician uses hypnotic techniques he "gives of himself to the patients. Even an hour's treatment with a very sick patient can produce an appreciable tiring of the hypnologist, and, as the sympathetic bond between the two grows stronger, the hypnologist may even 'feel' the symptoms he is trying to eradicate from the patient."

In brief, hypnotically induced analgesia appears to involve two essential factors: 1. The patient must have confidence in his physician and believe that hypnotic procedures can relieve his pain. 2. The patient must become inattentive to, not thinking about, and unresponsive to the nociceptive stimulation. To the extent that the first factor is operative, hypnotic analgesia resembles a placebo effect. To the extent that the second factor is operative, hypnotic analgesia resembles the relief of suffering achieved by administration of morphine and other opiates.

Hypnotic Analgesia as a Placebo Effect

In extensive studies of severe postoperative wound pain, Beecher[10] found that about 30% of patients received satisfactory relief from a placebo. (The term "satisfactory relief" refers to the patient's judgment that he has received "50% or more relief of pain at 45 and 90 minutes after the administration of the agent.") Others have carried out similar studies and have confirmed these findings. Although hypnotic procedures may offer a more satisfactory relief than placebos, this has not been experimentally demonstrated and requires further investigation.

How does a placebo minimize the suffering associated with postoperative wounds or other pain syndromes? As a first approximation to an answer, it is difficult to disagree with Wolf's[11] conclusion that "'placebo' actions depend for their force on the conviction of the patient that this or that effect would result. . . . The fact that 'placebo effects' occur depends, of course, on the generalization established repeatedly by numerous workers that the mechanisms of the human body are capable of reacting not only to direct physical and chemical stimulation but also to symbolic stimuli, words and events which have somehow acquired special meaning for the individual."

In general, studies of the placebo effect suggest that the placebo reactor is responding to a "drug" which he believes has curative properties.[1b] This belief is a function of many factors: what the patient is specifically told about the "drug," the patient's previous experience with pain and with drugs, and his previous experience with the physician, the nurses, and the other hospital personnel. Similarly, hypnotic analgesia is partly a function of the patient's conviction that the physician-hypnotist will relieve his pain, which in turn is a function of his previous experience with pain, with his physician, and with hypnotic procedures.

Hypnotic Analgesia and the Effect of Morphine

It has generally been assumed that hypnotic analgesia has little, if anything, in common with the relief of pain effected by administration of morphine. However, a careful scrutiny of the evidence suggests that these seemingly diverse analgesic agents actually possess common characteristics: in both, pain as a sensation is not necessarily altered; in both, discomfort and suffering are minimized or eliminated; in both, the relief of suffering appears to be secondary to an alteration in the patient's concern with, attention to, or anxiety about the nociceptive stimulation. Wolff and coworkers[12] concluded from a series of investigations that after morphine administration "the pain sensation is perceived and is recognized as pain with no difficulties." More recent clinical and experimental evidence indicating that morphine and other narcotics can relieve discomfort and suffering without necessarily elevating the pain threshold or altering the sensation of pain has been summarized by Beecher[10] and myself.[1b]

The relief of discomfort and suffering appears to be one component of a more generalized effect of morphine which has been conceptualized as "freedom from anxiety," "contentment," and "a bemused state." Beecher[10] wrote, after extensive clinical and experimental experience with morphine and other analgesics, that "the narcotics really alter pain perception very little but do produce a bemused state, comparable to distraction, which they [the patients] can be 'alerted out of' and will then report on the little altered pain perception." Along similar lines, Hill and co-workers[13] concluded from a series of experiments that the relief of suffering effected by morphine administration may be secondary to a more general effect (which they term the relief of anxiety or fear of pain) and that morphine may be effective as an analgesic agent only when anxiety is present.

In brief, narcotics and hypnotic procedures do not necessarily affect the sensation of pain per se; however, by mitigating anxiety and by inducing contentment and "a bemused state," discomfort and suffering are alleviated and the pain sensation may appear to be suppressed.

Summary and Conclusions

There is no need for such concepts as "trance," "suggestibility," or "the unconscious" to understand the relief of discomfort and suffering produced by hypnotic methods. To understand hypnotic analgesia the emphasis should be placed on the characteristics of those relatively few persons who are able to experience this phenomenon. As a result of previous life experience, these persons are able quickly and easily to become relatively inattentive to, not thinking about, and unresponsive to selected stimuli. Given this type of person, and given a belief on his part that his physician-hypnotist will relieve his pain, discomfort and suffering are minimized by two interrelated processes which are also effective when administration of placebos and morphine relieve a pain syndrome. First of all, suffering is minimized because a placebo effect is operating; that is, the patient believes that pain will be relieved. A second factor is similar to the effect of morphine; morphine administration and hypnotic procedures alleviate a pain syndrome primarily by bringing about contentment, freedom from anxiety, and "a bemused state comparable to distraction," without necessarily altering the intensity of the painful sensation or elevating the pain threshold.

HYPNOSIS—APPLICATIONS AND MISAPPLICATIONS

Harold Rosen, M.D., Ph.D., Baltimore

Hypnotic techniques can be readily taught. The only apparatus needed is the vocal apparatus of the physician hypnotizing the patient. But theoretically unsound and mutually inconsistent statements are made in this field, particularly in promotional material for fixation objects and hotel-room courses. Cases here described show that neither diagnostic uncovering techniques nor supposedly therapeutic chronological regression with abreaction is safe in the hands of persons ignorant of psychodynamics. Failures are as melodramatic as successes. No one should ever treat patients on hypnotic levels for therapeutic goals or with techniques beyond the range of his usual professional competence with unhypnotized patients. Used with due caution, however, hypnotic techniques have tremendous potentialities in medical practice.

Hypnosis will, in all probability, turn out to be a potent medical research tool.[1] It is even now of pronounced value in clinical practice. Hypnotic techniques, although they do not of themselves constitute treatment, may help to make it possible, in selected patients, to control physical and emotional pain, to allay anxiety and apprehension, and by mere verbal suggestion to cause even incapacitating symptoms to disappear.

About 25% of the general population—figures in the literature vary from 15 to 35%—may be hypnotized deeply enough, in a short enough period of time, for hypnotic induction techniques to be clinically usable by physicians. Patients can be hypnotized whether they are standing up, sitting on a chair, or lying in a hospital bed. They can be hypnotized whether they wish to be or not. They can be hypnotized without conscious awareness on their part that hypnotic induction is being attempted.

Chairman, Committee on Hypnosis, Council on Mental Health, American Medical Association.

Read in the Symposium on Hypnosis before the Joint Meeting of the Section on Anesthesiology and the Section on Nervous and Mental Diseases at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 11, 1959.

They can be hypnotized by suggesting eyelid closure; yet even during the first induction process their eyelids may never be closed.

Techniques of Hypnosis

Most induction techniques make use of the voice. Physicians by training are accustomed to the use of drugs and as a result some colleagues feel more comfortable if intravenously given barbiturates, such as thiopental (Pentothal) or amobarbital (Amytal) sodium, or other chemotherapeutic agents are prescribed. For most patients, however, this is not necessary. Some colleagues use fixation objects and have patients focus on a spot on the wall or ceiling, on a finger, eye, or pen, or on a glittering object. These may cost a few cents or a few hundred dollars, depending on how elaborate they are and how much science fiction and science fantasy—in the form of theoretically unsound statements or misstatements about brain-wave tracings, extrasensory perception, or whatnot—are emphasized in the promotional material. Neither drugs nor machines, however, are needed. The spoken word is usually more than sufficient.

A large number of oral induction techniques have been described.[2] The classic ones—and it is these that are taught physicians—are characterized by monotonous suggestions that the patient feel relaxed, breathe deeply but comfortably, close his eyes, and feel sleepy or fall asleep. It may be added that he will—or will not—remember, forget, or misremember whatever he does, says, or feels while hypnotized. Posthypnotic suggestions can be given him. If analgesia or anesthesia is the desideratum, for obstetric or surgical purposes, he may be told that he feels nothing or, alternatively, that whatever it is that he does feel will not annoy, disturb, pain, or otherwise affect him. Dry runs—rehearsal deliveries or rehearsal operations—may also be carried out.

The only apparatus needed for this is the vocal apparatus of the physician hypnotizing the patient. As a result, hypnotic techniques can be readily taught. For most physicians 15 to 30 minutes' instruction is more than sufficient. It seems little short of magical that so much can be accomplished through techniques so readily mastered. But, unless the physician has had adequate training in psychodynamics, hypnosis may be extremely dangerous for his patient without his realizing it.[3]

Results are nevertheless startlingly melodramatic. So, incidentally, are failures. Some colleagues hypnotize patients for preoperative sedation, others to set fractures. The value of hypnosis in physical medicine during the rehabilitative process is self-evident. Most articles emphasize its value as an analgesic, anesthetic, or tranquilizer. Some urologists, without using the word "hypnosis," over a two-minute or three-minute period attempt to hypnotize patients for catheterization. If they succeed, the patient is much less uncomfortable than he otherwise might be; if it does not "take," only a few minutes has been lost; and the patient is catheterized in either case.

Indications and Contraindications

Patients can be hypnotized in medical practice for a number of other reasons as well. The patient who has had a heart attack, for instance, like the patient with peripheral vascular disease for whom surgery is recommended, may find it difficult or impossible to smoke less or to cease smoking. His tobacco intake may be blocked by posthypnotic suggestion. The patient with severe pruritus (from poison ivy, for example, or a trichomonal infection) may posthypnotically no longer be plagued by the itch. Obese patients may posthypnotically adhere to the optimal diets prescribed and lose weight without regaining it later on. Patients with neurotic or psychotic diseases may be hypnotized and cure of symptoms suggested.

However, the physician in general practice or in one of the specialties who hypnotizes patients when he believes it indicated always attempts to determine in advance[3A] whether or not the patient can comfortably—and in his own best medical interests—carry out the suggestions given him. He guards against adverse effects. If smoking cigarettes, for example, is the only means that a particular patient with cardiovascular disease has of relieving his tension, he will give him some other tension-relieving device before stopping his smoking. Otherwise, with no means of letting off steam, his blood pressure level may increase up to 50 points, and apparently innocuous posthypnotic suggestions to decrease or cease smoking may impose an additional strain on an already over-burdened cardiovascular system and be harmful instead of helpful.

The same statement can be made about patients hypnotized for other reasons.[4] One patient whose severe generalized pruritus was hypnotically "suggested away" was almost overwhelmed with sexual desire for the lover who had deserted her immediately after procuring her abortion; furthermore, she now felt an almost homicidal rage against him. With the relief of her physical itch she now emotionally "itched"—I know of no other way by which to characterize it—both to possess and to kill him. It therefore seemed advisable to relieve her dermatological pruritus not by hypnotizing it away but by treating some of the emotional tension-producing factors which underlay it. A patient with phantom-limb pain that was successfully suggested away while he was hypnotized[2a] had to be hospitalized psychiatrically because of an underlying schizoaffective psychosis that, a short time later, erupted into overt symptom formation. Hypnosis, even with magical pain relief, can be dangerous.[3]

Summary of Casts

It is easy enough to hypnotize, but it is of prime importance to know when not to. For this reason, whenever patients request hypnosis their motivation for this and their reasons for requesting it need evaluation. One patient, for instance, after having dental work done under hypnosis, on several occasions persuaded her dentist to hypnotize her so that she would cease smoking. His posthypnotic suggestions were ineffective. She ultimately but reluctantly accepted referral for psychiatric consultation to determine why, despite strong hypnotic suggestion, she was unable to cut down on her cigarette intake. It appeared that she was a lonely widow who hoped her dentist would fall in love with her. She smoked only a few cigarettes a day, but seized on this to make further appointments with him. It took a one-and-one-half-hour interviewing session, however, to elicit this. Needless to say, she was not hypnotized by the psychiatrist.

Neither was a patient who three or four years previously had had a radical mastectomy. A nodule had appeared on her sternum and was now under investigation. She asked to be hypnotized so she could forget—and forget completely—that she had ever had cancer. During the consultation session it became evident that she was a very depressed woman. In view of the fact that she had had a malignancy and that a recurrence was in the offing, this was understandable. However, a number of slips of the tongue showed that only religious scruples had kept her from killing herself. She wished to blot out not only memory of her past cancer, not only memory of part of her past life, but her whole life itself. It became obvious, from further slips of the tongue, that she was not aware of this on conscious levels. Hypnosis to her would have been tantamount to permission to commit suicide. This was not called to her attention, nor was her husband told of this. Hypnotic induction was not attempted. Instead, both she and her husband were seen—although separately—over a few interviewing sessions, in order to help each reach the point of requesting psychiatric hospitalization for the treatment of her underlying emotional problems, while the possibility of recurrence of her cancer was being further investigated. This apparently minor but actually major therapeutic goal was achieved. She remained in the psychiatric department of the hospital for several months. This was some years ago, and the patient is still alive and is well.

This patient in all probability was readily hypnotizable. It is highly probable that with strong hypnotic suggestion she could have become amnesic for her mastectomy and her cancer. Neither she nor her husband would have seen any correlation between what to them would have appeared a miraculous hypnotic cure and her later suicide. Despite the probability of her self-inflicted death, her husband would have remained grateful to the physician, if he had hypnotized her, for having helped her so much before the end.

Some colleagues may consider this an extreme example, but it illustrates the problem with the sharpness of caricature. It is of prime importance to know when not to hypnotize. There is no dearth of illustrative case material. For instance, a compulsive smoker in her 30's was given a posthypnotic suggestion to cease chain-smoking. The suggestion was effective. She was grateful to her hypnotist, felt that he had "cured" her of cigarette smoking, and did not correlate her present distaste for cigarettes with the compulsive overeating that soon took its place. By the time she had added 40 lb. (18.2 kg.) to her weight, she sought out a second hypnotist who "cured" her of her obesity. She then—but much later—gradually began drinking more and more, found herself too intoxicated one day to attend to routine social commitments, and requested a third hypnotist to "cure" her alcoholism. To her, her compulsive chain-smoking, overeating, and alcohol intake were three completely unrelated problems. She spoke about each of her previous hypnotists in glowing terms. Her descriptions reminded one of quack cancer-cure testimonials made by patients a few months before they are hospitalized *in extremis.*

I have seen a number of patients who have been hypnotized by not one but several colleagues and about whom the same comment can be made. This is especially characteristic of the obese patient who after five or six months finds it impossible to retain her weight loss but who nevertheless on a follow-up questionnaire gives her hypnotist to understand that obesity is no longer a problem. She does not, so she states, wish to hurt her physician's feelings.

Abuses of Hypnosis

This is not to decry the use of hypnosis. Ever since Mesmer physicians have been impressed by apparent cures attained through direct hypnotic suggestion—and then disappointed. Although more effective than suggestion on nonhypnotic levels, hypnosis frequently is not sufficient. Follow-up studies over a prolonged period of time are indicated. Long-term studies[5] do not confirm short-term hopes. For this reason, if for no other, courses now offered by lay or professional personnel to dentists and physicians stress not only suggestion but chronological or age regression and abreaction. These techniques have been emphasized and re-emphasized in lay periodicals and in technical journals, as have uncovering techniques.

These therefore require further discussion. I have already mentioned a patient with diabetic gangrene who after a leg amputation developed phantom-limb pain that persisted after a neuronectomy, as a result of which narcotics ultimately were prescribed for him as needed. He was hypnotized and his pain was readily suggested away. It was not known if this was safe, since pain that persists for emotional rather than physical reasons frequently either is a depressive equivalent or serves to help hold a depression on leash. On investigation it turned out that this patient "knew" that like his wife before him he already had metastases, would need multiple surgery, would learn that this nevertheless was too late, and would like his wife die a lingering, agonizing death. Psychiatric treatment, preferably on a hospitalized basis, was recommended but refused. As long as he could concentrate on the pain in his stump he could forget or escape preoccupation with his underlying fears. With the relief of the pain [2a] he saw no reason for further treatment. Psychiatric hospitalization as a result ultimately became mandatory. It might have been better if while he had still had his pain a psychiatric treatment relationship had been established. This was attempted with a patient, reported by Joseph and co-workers,[3a] whose pruritus of six months' duration was hypnotically relieved and who then developed a psychotic depression.

Two other hypnotic techniques, time regression and abreaction, are usually taught physicians. Patients once hypnotized can be ordered to pass back through time to the event or events that, it is alleged, must be considered the cause of their asthma, epilepsy, torticollis, diabetes, headache, insomnia, back pain, alcoholism, or homosexuality. They are then told to relive (i.e., abreact) this emotionally traumatic event and be cured.

With traumatic neuroses this may be indicated, but it may not. Merely regressing a patient to a specific incident may or may not be helpful. With a Kentucky coal miner who had been caught in a cave-in, it was. His severe choking and gasping spells which on two occasions had been misdiagnosed as asthma disappeared, as did his almost constant feeling of being suffocated. An adolescent with a wry neck, however, when regressed in this way, relived a sexually traumatic episode and his torticollis immediately disappeared. The surgery for which he had been tentatively hospitalized became unnecessary; however, he then became an exhibitionistic practicing homosexual. He would perhaps have been better off if his wry neck had not been "cured" in this way.

The self-styled hypnoanalyst without years of psychiatric (and analytic) training can be a dangerous person to have around, and so can the self-appointed teacher of the subject. A patient with severe back pain persisting after a laminectomy was abreacted by one of these. His pain disappeared posthypnotically, and the following week he committed suicide by jumping out of an upper-story window. If his back pain was organically based, this abreaction was not indicated. If it were thought that emotional factors were partially or completely responsible for it, then psychiatric consultation or hospitalization should have been requested. Pain, it should be emphasized, if emotionally based or if continued for emotional reasons, frequently masks severe and even suicidal depressions or serves as their equivalent. No patient with back pain, phantom-limb pain, intra-abdominal or intracranial pain, or even atypical trifacial neuralgia pain should ever be approached on hypnotic levels, by dynamically untrained personnel, with techniques more potent than those of mere verbal suggestion. No one, in fact, should ever treat patients on hypnotic levels with techniques beyond the range of his usual professional competence with unhypnotized patients.[6]

The literature is filled with direct misstatements of fact in this area. One frequently reads that psychotic patients cannot be hypnotized or can be hypnotized only with such difficulty as to make their hypnosis clinically impractical or impossible. Persons who make such statements either have no first-hand knowledge of the subject or are unable to recognize psychosis when they see it. A number of cases [3] have been reported in the literature and additional case reports are now in publication.

The problem is a pronounced one, since large numbers of patients show somatic symptoms rather than disturbed behavior. Their diagnosis is what, for want of a better term, has been labeled a compensated (psychoneurotic, dissimulated, borderline, or masked) psychosis. Suggesting away a single symptom may be dangerous unless such patients have several symptoms to fall back on. A single symptom can often be the last defense against decompensation.[7]

It may perhaps be for this reason that, in so many of the two-day and three-day courses advertised for physicians and dentists, hypnosis has been characterized as a powerful uncovering technique. Articles are appearing frequently in current medical literature advocating its use to pin-point the cause of various hysterical symptoms and so-called psychosomatic diseases. This can be dangerous. A woman with ulcerative colitis, for instance, when hypnotized and regressed, acted out an incestuous episode which took place when she was 5 or 6 years of age with an older brother. One month after his funeral her ulcerative colitis became symptomatically severe enough to necessitate her first hospitalization. If she had been allowed to remember this material on nonhypnotic levels, she might in all probability have gone into an overt depressive or paranoid psychosis. It is not what is uncovered or learned that is of importance, but how this can be used to help the patient. And this would have been harmful, not helpful, to her at the time.

Uncovering techniques, incidentally, are not often used even in internal medicine. If a patient has a heart murmur or a coronary condition, no one would suggest intrathoracic surgery so that the cardiologist could see, and therefore understand, the exact nature and full extent of the patient's cardiac disease. No well-trained psychiatrist would do emotional surgery merely to lay bare emotional disease, since this would be equally dangerous to the patient and of no value to him. It is exceedingly melodramatic for the hypnotist who does this, but it should be discouraged.

Nevertheless, chronological regression with abreaction is advocated constantly. A recent book on hypnosis in dentistry is filled with example after example of the use—to me it seems the misuse—of these two techniques in dental practice. Announcements of two-day and three-day courses on hypnosis for physicians, of the type now flooding the country, invariably list these as among the subjects taught. Their instructing staffs, both medical and lay, seem to feel that with this they are teaching psychodynamics; they do not realize that only hypnotic techniques are being taught.

During the past several years a number of persons have started calling themselves "hypnotists to the medical profession." Some of these are now importuning hospitals for operating-room and delivery-room privileges, for the purpose of hypnotizing patients for surgery or childbirth.[8] They have no medical competence and little or no knowledge of the complex phenomena involved, know nothing about the motivational bases of human behavior, and in my opinion should be denied such privileges. As the A. M. A. "Report on Medical Use of Hypnosis" states, "The utilization of hypnotic techniques for therapeutic purposes should be restricted to individuals who are qualified by background and training to fulfill all the necessary criteria that are required for a full diagnosis of the illness which is to be treated."[6] These so-called hypnotists to the medical profession do not have this training, nor do those persons with little or no knowledge of psychodynamics who wander from city to city, sending announcements to all physicians and dentists in the telephone book, and advertising one-day, two-day, or three-day hotel room courses which stress induction and potentially dangerous uncovering techniques.[7]

Summary

Hypnotic techniques have tremendous potentialities in medical practice. They can be used for sedative, analgesic, or anesthetic purposes; to make symptoms disappear; for tranquilization; or as an adjunctive technique when patients with neurotic or psychotic disease are under treatment. Before patients are hypnotized, their physical and emotional status and their motivation for seeking hypnosis need evaluation. For this, training in psychodynamics (the motivational bases of human behavior) is essential.

Results achieved depend to a large extent on the relationship between physician, or hypnotist, and patient, or subject. If such relationships are not understood, harm can result. Indiscriminate hypnosis may be dangerous. When physicians, whether in general practice or in the various specialties, use hypnotic techniques, it should be for purposes of and with techniques related to the particular specialties and within, not beyond, the range of usual professional competence when patients are seen and treated on nonhypnotic levels. We are otherwise playing with dynamite.

BRONCHIOLITIS IN INFANTS

PROBLEM IN PRACTICE

James L. Dennis, M.D., W. Martin Palmer, M.D.
and
Robert W. Cleveland, M.D., Oakland, Calif.

Bronchiolitis is a term applied to any inflammatory disease which afflicts the bronchioles. When it occurs in infants of less than 1½ years of age, it produces a distinct syndrome. The hospital charts of 1,200 children with bronchiolitis were reviewed for data on the salient features of the syndrome. It usually started with a mild upper respiratory infection. In the acute phase, obstruction of the bronchioles developed due to inflammatory edema and exudation; the resultant manifestations in the patient were dyspnea, cough, expiratory wheezing, and emphysema. This syndrome resembles that observed in the child with asthma who has an upper respiratory infection, but it differs in prognosis and in the fact that the infant with bronchiolitis does not improve after administration of epinephrine. The treatment is generally supportive but must be varied for the individual patient; it is directed toward the prevention of fatal complications, the most common being secondary bacterial bronchopneumonia and right heart failure.

The word bronchiolitis is a general term applicable to any inflammation of the bronchioles. Although many different viral, bacterial, or allergenic agents might initiate such a process in any person at any age, the clinical picture of infectious bronchiolitis in infants constitutes a distinct pediatric syndrome.

During the 10-year period 1947-1957, bronchiolitis was exceeded only by diarrhea as a cause for admission to the infant wards of the Children's Hospital of the East Bay. More than 1,200 of these cases have been reviewed to provide the basis for this report. In 483 (40%) the baby had been considered to be in critical condition at some time during the hospital stay, and in 2% the baby did not survive.

In spite of the common occurrence, serious morbidity, and definite mortality from this syndrome, many physicians appear to be unfamiliar with infectious bronchiolitis in infants. Almost invariably, the allergist, the internist, and the generalist referred to bronchiolitis as "asthma." Fifty-one per cent of the pediatricians used bronchiolitis as a diagnostic term when the patient was admitted; the rest used various designations, including asthma, asthmatic bronchitis, capillary bronchitis, interstitial pneumonia, pneumonitis, and acute emphysema. Apparently there is a problem in meaning as well as in understanding.

Clinical Features

The clinical course of infectious bronchiolitis in the infant is fairly constant. A "cold" or a simple respiratory infection of several days' duration precedes an acute onset of dyspnea, cough, expiratory wheezing, and emphysema that often becomes progressively worse in spite of treatment. This alarming period of respiratory distress persists for an average of two to three days and is followed by another two or three days of clearing by lysis. In 70% of patients the temperatures remained under 101 F (38.3 C), but they ranged between 98 and 105 F (36.7 and 40.6 C).

Subtle features related to the anatomic and physiological peculiarities of the infant are important to an understanding of the syndrome in this age group. It is known that with inspiration the bronchioles increase in diameter and that on expiration they diminish in size. For this reason, the presence of bronchospasm, hyperemia, edema, cellular debris, or mucopurulent exudate will result in varying degrees of obstruction that become apparent only during expiration. As air is trapped, emphysema develops. Eventually the diaphragm is compressed and flattened so that vertical excursion is no longer possible. However, with each inspiration, the powerful diaphragmatic muscle continues to contract, exerting a forceful pull on its attachments to the chest wall. The rigid, bony cage of the older child and adult can resist this force; the soft, elastic thorax of the baby can only collapse inward. This produces a unique paradox, characterized by prominent inspiratory retraction of the lower chest and sternum in a condition that is primarily a problem of expiratory obstruction, a distinctive set of circumstances found at no other time in life. In our series 98% of the babies who presented this picture were under 18 months of age, and 92% were under 12 months of age.

Causal Factors.—Although many authorities [1] have demonstrated the role of viruses and others [2] have isolated common bacterial pathogens from

Read before the Section on Pediatrics at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 9, 1959.

babies with bronchiolitis, many physicians persistently regard and treat this disorder as a manifestation of allergy.[3]

The possibility that hypersensitivity is a factor in bronchiolitis cannot be ignored. We have explored several areas that might elucidate this problem. In follow-up studies of 400 children who had been hospitalized for bronchiolitis as infants, only 33 (8.8%) gave a history of more than one episode of bronchiolitis, and only 12 of the children had definitely developed asthma. In contrast, a retrospective study of 100 asthmatic children revealed that more than half (54%) of them had repeated episodes of "bronchiolitis" during infancy.

Because of the almost specific effects of epinephrine in patients with asthma, a survey of the response to epinephrine was accomplished. Of the 1,200 hospitalized patients reviewed, 780 babies had been given epinephrine as a part of the initial medication. In only 39 (5%) was there an unqualified sustained clinical response. The seriously ill infant with infectious bronchiolitis is suffering from mechanical obstruction of the tiny bronchioles by inflammatory edema and exudate. In asthma, and possibly in the early stages of bronchiolitis, the major component of the obstructive force is bronchospasm; hence, symptoms are often—and sometimes dramatically—relieved by administration of epinephrine. This suggests that epinephrine administration might provide a diagnostic and prognostic test in an infant with symptoms of bronchiolitis.

The possible relationship of nasal eosinophilia and allergic disease has been considered. Nasal smears were obtained from 25 infants with bronchiolitis (with use of the technique described by Hansel[3a]). No consistent pattern was discernible, and the incidence of increased nasal eosinophilia was no higher in the babies who had bronchiolitis than in a control group of babies.

For the past two years we have obtained total blood eosinophil counts from babies with bronchiolitis. Normally, the total circulating eosinophil count in an infant will range between 100 to 300 per cubic millimeter. A stimulation of the "alarm reaction" by the stress of an infection can be expected to produce a drop in this number to between 0 and 25. Thus, a relatively high total circulating eosinophil count might indicate inadequate adrenal response to the stress of infection or the presence of a definite allergy. Eosinophil counts were obtained from 187 babies with bronchiolitis, and in only 6 (3%) was there a total count above 50. In 9 babies (4.8%) the eosinophil counts ranged between 25 and 50, and in 172 (91.5%) the count was between 0 and 25. One must concede the limitations of this simple, inexpensive laboratory procedure, but it may have practical application as a guide for the selective use of adrenal corticosteroids in the treatment of bronchiolitis.

Turning our interest to the infectious aspect of bronchiolitis, we conducted a survey of the families of 256 babies with bronchiolitis. In 93% of the cases respiratory infection had been present in other members of the family concurrent with the baby's illness. Like "croup," bronchiolitis occurred in small, epidemic periods; when one patient was admitted to the hospital it was usually the signal for several more to follow. The "cold" preceding the onset of symptoms, the presence of respiratory infection in family contacts, and the epidemic features of bronchiolitis appear to support the etiological role of the virus. Bacterial infection with Hemophilus influenzae, staphylococci, and pneumococci probably, in most instances, represent complicating secondary involvement.

Treatment

Few conditions in pediatrics evoke the multitude of routine orders that are provided the baby with bronchiolitis. The fact that the average length of the hospital stay for a patient with bronchiolitis (six days) was not altered during the 10-year period reviewed appears to be the most appropriate comment that can be made. The spectrum of therapy is outlined in the table. It is easier to discuss the inadequacies of therapy than it is to isolate factors that are of unquestioned value. The following program has, in our experience, been a positive and efficacious one.

General Supportive Measures.—Parenterally given fluids are prescribed when a baby is too ill to eat or drink or when there is dehydration. Fluids are given in sufficient quantity to cover insensible water losses and urine output. Electrolytes are added as indicated, and calories are provided by administration of glucose. Little attention has been accorded this aspect of therapy in infants with bronchiolitis, but the maintenance of adequate renal flow and glycogen stores is necessary to prevent metabolic acidosis from becoming superimposed on a respiratory acidosis.

Oxygen.—A 40% concentration of oxygen is maintained by continuous nebulization. The mist, or aerosol, provided by nebulization of distilled water (with or without wetting agents) creates a high-humidity atmosphere, minimizes insensible water loss, neutralizes the drying action of oxygen, and assists in the liquefaction of secretions.[4]

Antibiotics.—We do not advocate the routine use of antibiotics as prophylactic agents, but when a baby with bronchiolitis develops leukocytosis, high fever, and clinical signs of bacterial infection, we obtain appropriate cultures and initiate antibiotic therapy. Until cultures dictate otherwise, a program of chloramphenicol, 50 to 100 mg. per kilogram of body weight per day, and penicillin, 600,000 units per day, is preferred because of the high incidence of Hemophilus influenzae, staphylococcus, and pneumococcus infections in patients with the terminal bronchopneumonias of bronchiolitis. In our series the mortality rate dropped from 5% in 1947 to 2% in 1957. Although it was not possible to establish an unequivocal correlation with any particular mode of therapy, the most important single factor appears to have been the control of fatal, secondary bronchopneumonias by the use of antibiotics.

Spectrum of Therapy for Bronchiolitis

1. Oxygen
   40% in continuous nebulization
2. Liquefying Agents
   a. Aerosol mists (wetting agents, e. g., sterile aqueous solution of Superinone [oxyethylated tertiary octylphenolformaldehyde polymer] in combination with glycerine and sodium bicarbonate [Alevaire] and glycerine and propylene glycol, 2.5% each, in distilled water [Mistogen])
   b. Enzymes (e.g., proteolytic trypsin, desoxyribonuclease, crystalline trypsin [Parenzymel])
   c. Expectorant drugs (e. g., iodides, ipecac)
3. Bronchodilating Agents
   a. Epinephrine, ephedrine, phenylephrine (Neo-Synephrine) hydrochloride (prescribed to relax bronchospasm; not too effective in bronchiolitis and may have undesirable side-effects)
   b. Isoproterenol (Isuprel) hydrochloride; 1:200 dilution is effective by mouth or in an aerosol; may be used in patients with heart failure
   c. Xanthines: aminophylline, most widely used. Smooth muscle relaxant vasodilator and expectorant effects not prominently helpful to infants with bronchiolitis. Dose as rectal suppository should not exceed 7 mg./kg. of body weight (see text)
4. Mucosal Shrinking Agents
   a. Ephedrine or phenylephrine in mists or nose drops, as 0.05 to 0.1% solutions. Should be used for short intervals because of hypertensive and central nervous system effects. Ephedrine augments toxic effects of aminophylline
5. Antibiotics
   Prevention of fatal secondary bacterial infection is a goal in treatment. Hemophilus influenzae, staphylococci, and pneumococci are common pathogens; hence chloramphenicol, 50 mg./kg., and penicillin, 500,000 units, daily
6. Digitalis
   Digoxin, .075 mg./kg.
   Digitoxin, .035 mg./kg (see discussion in text)
7. Intermittent Positive-Pressure Breathing
   Controlled oxygen delivery with positive pressures, said directly to dilate bronchi, stimulate cough, wash out CO_2. Requires specialized equipment and experienced operators
8. Corticosteroid Hormones
   Indications not established (see text for discussion)
9. General Supportive Meaures
   Fluids, electrolytes, calories; by parenteral route if baby is not eating and drinking

Digitalization.—The occurrence of right heart failure in babies with severe bronchiolitis has not been widely recognized.[5] Admittedly, heart failure is difficult to evaluate when dyspnea, tachycardia, and a depressed liver constitute part of the primary illness; but if there is a persistently critical condition, tachycardia of 180 or more per minute, gallop rhythm, and a sudden, unexplained increase in the size of the liver, we digitalize. Digoxin, 0.075 mg. per kilogram of body weight, has been most efficacious in reversing these signs.

Other Modalities.—The preceding measures are of unquestioned value. Two other therapeutic measures that we are currently evaluating in controlled studies are intermittent positive-pressure breathing and use of adrenal cortical steroids.

Intermittent Positive-Pressure Breathing: Intermittent positive-pressure breathing requires specialized equipment for use in infants and the presence of a skilled operator. On occasion, this technique has appeared to be useful in correcting acute carbon dioxide retention, with respiratory acidosis. A few bursts of oxygen with controlled pressure stimulates cough and bronchial dilation and appears to improve ventilation.

Adrenal Cortical Hormones: Although we have consistently opposed the use of adrenal cortical hormones in patients with bronchiolitis, we have been impressed by some recent experiences with a new intravenous preparation, methylprednisolone sodium succinate (Solu-Medrol). In a pilot study this has been dramatically effective and without undesirable side-effects. However, the final answer must await prolonged and intensive observation under controlled conditions.

The fact that one physician out of three prescribes adrenal cortical hormones in the treatment of bronchiolitis deserves consideration. There is no evidence that adrenal insufficiency is a primary factor in patients with bronchiolitis; corticosteroids are not bronchodilating agents; and most authorities agree, in principle at least, that corticosteroids should not be used in patients with unknown infections.

Proponents may argue that adrenal cortical hormones are the most effective anti-inflammatory agents at our disposal and that, in spite of theoretical objections, they may be used with relative safety in short-term, self-limited infections, particularly when their use is covered by appropriate antibiotics.

In the cases reviewed, various corticosteroids appeared to modify the early critical phase of bronchiolitis in only an occasional instance. But this was difficult to evaluate, since similar responses were sometimes seen in babies who had not received hormones. Of interest is the fact that the average hospital stay for the babies who had received steroids was six days, identical to that for infants who did not receive steroids.

Until indications have been better established, we believe that corticosteroids should be reserved for use in certain rare occasions only; namely, those desperate situations in which all other therapy has been futile; when there is present an identified bacterial infection amenable to an available antibiotic; and for those instances in which the total circulating eosinophil count is elevated.

Summary

The cardinal manifestation of bronchiolitis from any cause is expiratory wheezing; therefore, "All that wheezes is not asthma." Bronchiolitis in infants is nearly always the result of an infection, usually a virus, producing a typical age-group response to a simple respiratory infection that only mildly inconveniences the adult. Asthma can induce a similar picture, but its symptoms are often alleviated by epinephrine, its typical course is short, and repeated attacks are common. The infant with a single episode of infectious bronchiolitis is quite unlikely to develop asthma in later life, but most asthmatic children have been subject to attacks of bronchiolitis as infants. The tendency to overtreat infants with bronchiolitis probably reflects the lack of specificity of any mode of therapy. Although many new therapeutic agents have been prescribed, the average length of the hospital stay has not been altered in the 10-year period 1947-1957. Aminophylline poisoning, due to excessive dosage in rectal suppositories, has become one of the most frequent complications of therapy. For these reasons, treatment should be directed toward general supportive measures and the prevention of potentially fatal complications, the most common being bronchopneumonia, right heart failure, fluid and electrolyte imbalance, and iatrogenic drug intoxication.

The methylprednisolone used in this study was supplied for investigative purposes as Solu-Medrol by the Upjohn *Company, Kalamazoo, Mich.*

EXTRADURAL OSSEOUS LESIONS SIMULATING THE DISK SYNDROME

Harry R. Walker, M.D., Oakland, Calif.

Seven patients with complaints and physical findings suggesting a diagnosis of herniated intervertebral cartilage (disk syndrome) were found, on more thorough study, to have neoplastic disease of the bone. Roentgenographic examinations were done to show the vertebrae in better detail than before and to survey bones other than the vertebrae. In three patients the neoplastic process involved lumbar or sacral vertebrae, but in three others it involved the pelvis and in the seventh it involved the femur. In cases of supposed disk syndrome a thorough study of the rest of the skeleton should be done before elective surgery is attempted on the vertebral column.

During the last 20 years I have been confronted with many problems in orthopedic surgery but none so complex as the diagnosis and treatment of lesions of the lower part of the back, namely, the lumbosacral spine and pelvis. This paper pertains to one aspect of the problem of the low back, that of osseous lesions which simulate a common entity, the disk syndrome. I think all physicians, after 25 years of development, believe they can diagnose a herniated disk, particularly with the aid of a neurologist and with use of myelograms. However, these lesions I am about to describe frequently have not been looked for or have been neglected or overlooked by the neurosurgeon, the orthopedist, or the radiologist. While some of them are not common, they are more common than one anticipates and should be considered in most diagnoses.

Read before the Section on Orthopedic Surgery at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 10, 1959.

I have encountered seven cases, which will illustrate some of the things that can be misconstrued or misdiagnosed. They are, in my mind, major orthopedic problems.

Report of Cases

Case 1.—A 20-year-old man was inducted in the armed services one year prior to his admission to the naval hospital in Oakland. On admission he was in obvious distress and was reluctant to move because of pain in his back which radiated down into his right leg. He had had an insidious onset of pain in the lower part of his back after gunner exercise, in which he was required to lift heavy shell casings. He was put to bed for two weeks and was then admitted to a base hospital with a diagnosis of a herniated disk. Then he was returned to the mainland for further care. On admission he was uncomfortable, with pain in the back which extended down the right leg. He was found to have marked limitation of motion and muscle spasm in the lumbosacral area, with tenderness over the sacroiliac joint and along the course of the sciatic nerve. He had a strongly positive straight-leg-raising test on the right, with some hyperesthesia over the lateral aspect of the right calf. All reflexes were present and unimpaired. X-rays taken at a base hospital accompanied the patient and results were essentially negative when reviewed. His laboratory findings, consisting of results of blood studies and urinalyses, were within normal limits. He had a slight elevation of temperature for two days and an increase in the white blood cell count of about 1,000 per cubic millimeter, with some elevation of the sedimentation rate. His symptoms increased, in spite of traction, while he was in the hospital. On the third day he was given an enema, and roentgenograms were made of the lumbosacral spine and pelvis which showed a lesion that was suggestive of malignancy in the right sacroiliac joint. A biopsy specimen revealed Ewing's sarcoma. No other surgery was contemplated, and he was treated by radiation therapy.

Case 2.—A man about 69 years of age had a history of an insidious onset of low back pain, which radiated down the posterior aspect of the thigh, about six years ago. He was first examined by a general practitioner in a western city and then referred to a neurosurgeon who performed a laminectomy on the right side between L-4 and L-5, without relief of his symptoms. Two years later he had another laminectomy, and this too proved futile. The interspace between L-4 and L-5 was explored. Degenerated disk material was excised and removed. The patient felt better for a while; then his former symptoms recurred, and he developed a slight limp on the right side. Eighteen months later he had another exploratory laminectomy with a spinal fusion between L-4 and L-5. As soon as he had recovered from this operation his former symptoms recurred, and one year later he was referred to a large clinic in the middle west.

Physical examination revealed slight limitation of motion in the lumbosacral spine, multiple operative scars over the lower part of the back, atrophy of the right gluteus muscle, and tenderness over the lumbosacral spine, the sacroiliac joint, and the posterior aspect of the hip and down the course of the sciatic nerve to the knee. The results of his neurological examinations were negative, except for a diminished ankle jerk and positive straight-leg-raising test result. The hip joint functioned well. He had a full range of motion in all planes, and there was no weakness of any muscles other than those of the gluteal group. There was no measurable atrophy of the calves; however, there was about 0.5 in. of atrophy of the right thigh. Results of x-ray examinations of the lumbosacral spine were negative, with the exception of the surgical defect and the fusion in the lumbosacral area between L-4, L-5, and S-1. Review of all of his roentgenograms revealed that he had not had an x-ray examination of the pelvis which included both hips. This was taken to complete the series. I found a lesion on the neck and posterior aspect of the femur which was found to be a chondrosarcoma, grade 2, and which was removed.

Case 3.—A man was first seen in 1952, complaining of pain in his back which radiated into his right leg for about four years. There was no history of trauma. He was found to have limitation of motion in the lumbosacral area and muscle spasm of a moderate degree. There was tenderness along the course of the sciatic nerve but none over the sacroiliac. He had a positive straight-leg-raising test result on the right and some hypesthesia over the lateral aspect of the thigh and calf on the involved side. There was full range of motion in the hips, knees, and ankles. Myelograms were taken, and it was thought there might possibly be a degenerated disk between L-4 and L-5 on the involved side. When a laminectomy was performed, a large amount of degenerated disk material was excised and removed at the L-4, L-5 level on the right. The pain subsided in his back and leg, but his gait failed to improve. Three months later it became increasingly difficult for him to flex his thigh, and his straight-leg test result became more positive; however, he still had a full range of motion in the hips, knees, and ankles. Since he had not had a roentgenogram of the pelvis which included the hips, such a film was taken; it showed some cloudiness, which we thought was a lesion in the ilium, superior and posterior to the acetabulum. A biopsy was taken and it was first diagnosed as an osteoid-osteoma but later was shown to be a chondrosarcoma.

Case 4.—The next patient, who was referred to me by another doctor, had an acute onset of pain in his back and gave a history of having had similar attacks previously. He was admitted to the hospital and placed in traction. The laboratory report showed a slight increase in the sedimentation rate but nothing abnormal in the complete blood count or urinalysis. He had marked muscle spasm and limitation of motion of the entire dorsal and lumbosacral spine. The pain radiated into both legs, more marked on the right than the left. He had a strongly positive straight-leg-raising test result, hypesthesia, with occasional numbness, in the right leg, and a diminished knee jerk on the right side. An incidental finding in the x-rays was what seemed to be some punched-out lesions in the scapula. Additional x-rays were taken, and a biopsy was performed on the bone. The patient was found to have multiple myelomas.

Case 5.—A 32-year-old woman developed pain in her back during a pregnancy in the early part of 1958. After delivery of a normal child in the fall she still had pain, which extended down her right leg. When the patient was examined in the hospital in November, 1958, a diagnosis of low back pain with sciatica, probably due to a herniated disk, was made, x-rays were taken, and conservative treatment was instituted. In December her condition had not improved, and a myelogram showed a large defect between L-4 and L-5. A laminectomy was performed in February, 1959, and a large disk. which protruded posteriorly, was removed. She continued to have pain in the back, although the sciatica was much relieved. The pain became more severe, and later she developed sciatica. X-rays taken at this time showed an osteolytic lesion involving the fifth lumbar vertebra. A biopsy specimen taken of the fifth lumbar vertebra proved to be a giant-cell tumor.

Case 6.—A 20-year-old woman had a history of onset of pain in the lower part of her back three days before she was first examined in a clinic in Japan. She was in the fourth month of her first pregnancy. The severe pain was in her back, over the right buttock and radiating down into the right leg, thigh, and knee. She had a positive straight-leg-raising test result on the right, with limitation of motion and muscle spasm in her back and tenderness over the course of the right sacroiliac and right sciatic nerve. She had full range of motion in the hips, knees, and ankles with no atrophy or deformity of the thighs or calves. Results of neurological examinations were negative at that time, with the exception of some hypesthesia over the lateral aspect of the right calf. When the patient returned to the United States the pain in her hip and back had become more severe. On arrival she was walking with a limp and had limitation of motion in all planes of the right hip. X-rays revealed some thinning out and some osteoporosis and decalcification in the region of the right ilium. Biopsy specimens were taken and the diagnosis was reticulum-cell sarcoma.

Case 7.—A 40-year-old woman was first seen in the office in 1955, with a history of several psychiatric episodes over the past few years. She complained of pain in her back, with constant radiation of pain down her left leg, and she was seen by several doctors. Results of examination were essentially negative, with the exception of a diminished ankle jerk on the involved side. Myelograms showed a possible herniated disk between L-5 and S-1 on the left side; however, after several months, she developed weakness in the lower part of the leg and the ankle jerk became completely obliterated. During performance of a laminectomy, I failed to find a herniated disk but I did find some degenerated disk material. The nerve roots in this area had a peculiar appearance. The areas above and below were explored for any possible involvement of the nerve roots but none was found, other than an enlarged ganglion at the lower portion of the fifth lumbar nerve.

After operation, the weakness continued in the lower part of her leg, and she subsequently developed drop foot. A few months later, on reexploration, a large, gelatinous, gray-red tumor was found in the top of the sacrum, about 0.5 in. below the fifth interspace. When this was removed, a medicine glass full of tumor material was obtained. Frozen sections at the time of surgery were reported as nonmalignant; however, on permanent section, it was diagnosed as a neurofibroma. This patient is still alive but is now paralyzed from the fifth lumbar vertebra down. The mass has spread into her pelvis and over areas of her buttocks.

Comment

These patients with extradural osseous lesions simulating the disk syndrome had (case 1) Ewing's tumor of the pelvis; (case 2) multiple myelomas of the lumbosacral spine; (case 3) reticulum cell sarcoma of the right ilium; (case 4) chondrosarcoma of the pelvis; (case 5) chondrosarcoma of the femur; (case 6) neurofibroma of the sacrum; and (case 7) giant-cell tumor of the fifth lumbar vertebra. The patients with Ewing's sarcoma, multiple myelomas, and reticulum cell sarcoma all died within one year of the onset of the symptoms and within one year of the time the diagnosis was made. The patients with chondrosarcoma both died within two years of operation and establishment of correct diagnoses. However, it was obvious that both had had symptoms for as long as five years previously. The patient with neurofibroma is alive but *in extremis*. At present the patient with the giant-cell tumor of the fifth lumbar vertebra is not ambulant and is having neurological difficulties with the lower parts of the legs and difficulty with elimination.

Summary

Seven patients had extradural osseous lesions simulating the disk syndrome. All had symptoms and findings similar to those of an intervertebral disk lesion, with nerve-root irritation, and all at one time or another, had been diagnosed as having such. No surgery was performed on the patients with Ewing's sarcoma, multiple myelomas, or reticulum cell sarcoma, other than for diagnostic procedures. The remaining patients had multiple operations, and it was only after attempts to find an intervertebral disk lesion had been unsuccessful that the correct diagnosis was established. One must conclude that a thorough study of the osseous skeleton should precede any elective surgery of the spine and pelvis.

CLINICAL NOTES

CRUTCH WITH SLOPING HANDGRIP

Bert C. Wiley, M.D., Johnstown, Pa.

The physical medicine department of Conemaugh Valley Memorial Hospital, Johnstown, Pa., in cooperation with a crutch manufacturer, has made the first major improvement in axillary crutches since the current adjustable crutch was designed about 15 years ago.

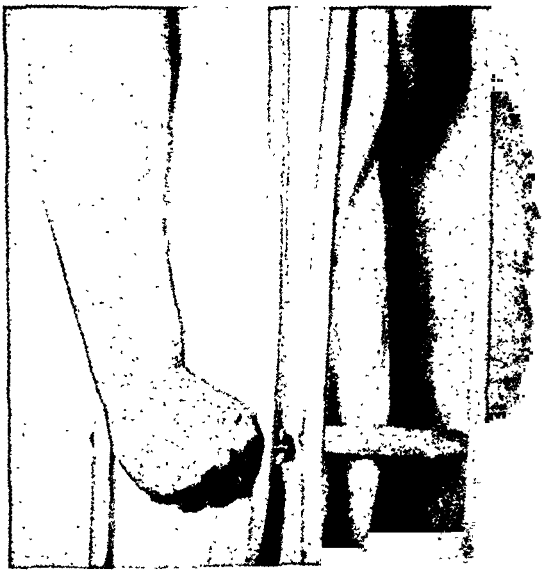

Fig. 1.—Conventional crutch with horizontal handgrip, showing excessive radial deviation of wrist.

Most persons who use axillary crutches quickly develop considerable soreness of the thenar eminence. Some patients have had to return to nonambulatory status because of thumb soreness, when an attempt was made to use crutches too soon. Many persons who routinely use axillary crutches develop painful calluses over the thenar eminence and numbness of the entire thumb. This additional disability is caused by the nonanatomic angle of the crutch handgrip (fig. 1).

When the normal wrist dorsiflexes in order to push against a handgrip, a line across the "heel" of the palm forms an angle of about 60 degrees with the length of the radius. This is at an angle of 30 degrees with the usual horizontal crutch handgrip.

The handgrip of the newly developed crutch (fig. 2) is set at an angle of 15 degrees with the horizontal. This, together with the normal 15 degree flexion of the elbow during crutch weight-bearing, permits the weight-bearing "heel" of the palm to rest evenly on the new handgrip. Even patients with marked deformity of the hand due to rheumatoid arthritis report a very significant increase in hand comfort when using the new crutch. An additional advantage is that it cannot be used "backward" because of the slope of the handle.

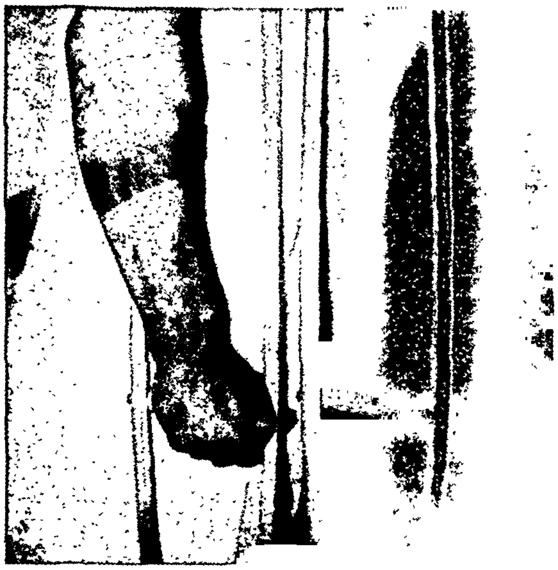

Fig. 2.—New crutch with sloping handgrip, showing normal wrist alignment.

Director of Physical Medicine, Conemaugh Valley Memorial Hospital.

Therefore, the crutch-walker always keeps the wing-nuts forward, where they are less likely to cause injury during a fall. The standard range of adjustment for both crutch length and handgrip distance from the axillary crosspiece has been retained. The new crutches cost only about 25 cents per pair more than the previous conventional adjustable crutches.

A sloping handgrip crutch is not a new idea, since it is an alteration that many hospital shops have been making for two decades.[1]

ACUTE POSTOPERATIVE CARDIORESPIRATORY INSUFFICIENCY

TREATMENT BY CURARIZATION AND ARTIFICIAL BREATHING

Paul W. Sanger, M.D., Francis Robicsek, M.D., Frederick H. Taylor, M.D., Robert E. Stam, M.D.,
and
Terry T. Rees, M.D., Charlotte, N. C.

Cardiac insufficiency produces dyspnea. At the same time labored breathing per se compounds the work of the failing heart. This problem challenges the physician every day. The therapeutic approach commonly used to break this vicious cycle is that of decreasing the dyspnea by depressing the respiration. Granted this has advantages, such an approach must be applied cautiously, as excessive depression of respiration may increase the already existing anoxemia.

The introduction, by Björck,[1] of mechanically assisted respiration for acute cardiorespiratory insufficiency was an important therapeutic achievement. Assisted respiration does not, however, completely relieve excessive work of the heart when it is associated with labored breathing. Patients who are uncooperative and those who breathe against the machine may develop fatal exhaustion.

We faced such a problem in one of our patients who underwent direct-vision repair of a large interatrial septal defect complicated by severe pulmonary hypertension. On the third postoperative day he developed acute cardiorespiratory failure which did not respond to the usual therapeutic measures. We attempted to relieve this patient of his severe dyspnea by prolonged curarization and artificial breathing.

Report of a Case

On Feb. 23, 1959, a 10-year-old boy was admitted to the department of thoracic surgery at Charlotte Memorial Hospital. He was known to have had heart disease since birth. At the time of admission the boy was in heart failure and in poor general condition. The clinical examination suggested an interatrial septal defect with pulmonary hypertension and bidirectional shunt. This diagnosis was confirmed by heart catheterization. Right ventricular pressure was 110/6 mm. Hg, and the pressure in the pulmonary artery was 90/38 mm. Hg. His systemic arterial oxygen saturation was 90%. The systemic blood flow was calculated as 2.32 liters per minute, with the pulmonary flow 4.00 liters per minute. The left-to-right shunt at the atrial level was 2.26 liters per minute and the right-to-left shunt 0.58 liters per minute. The pulmonary arteriolar resistance was found to be increased to 810 dyne-cm.$^{-5}$ per second.

After three weeks of intensive medical treatment which included bed rest, administration of digitalis and diuretics, and a low-sodium diet, the patient's condition showed moderate improvement. His peripheral edema disappeared; his liver became smaller, and his dyspnea at rest ceased. It was decided to repair the interatrial communication.

At operation the heart was found to be enormously enlarged and the pulmonary artery was about three times larger than the aorta. Cardiopulmonary bypass was begun[2] and the right atrium was entered. We found a secundum type of septal defect, about 3 cm. in diameter. Two-thirds of this defect was closed, but one-third was left open as an emergency vent for the overloaded right ventricle. The patient tolerated the 15 minutes of total body perfusion. His first postoperative day was uneventful.

On the night of the second day after the operation the patient developed excessive bronchial secretions. Intratracheal suction was performed repeatedly. Blood pressure and pulse rate remained relatively stable, and his color was good.

From the Department of Thoracic Surgery and the Heineman Cardiopulmonary Research Laboratory, Charlotte Memorial Hospital.

On the third postoperative day the patient's general condition showed progressive deterioration. *Portable chest x-ray film revealed partial atelectasis* of both lungs. A tracheostomy was performed. Late in the morning he had two attacks of pulmonary edema and his dyspnea became extremely severe. The blood pressure fell to 65 mm. Hg systolic, and the pulse rate was 160 per minute. Bronchoscopic aspiration was performed through the tracheostomy, the dosage of digitalis was increased, and infusion of phenylephrine (Neo-synephrine) hydrochloride was started. The tracheostomy cannula was attached to a Bennett respirator, but failure of the patient to cooperate forced us to discontinue this assisted breathing. During the afternoon the patient developed mediastinal emphysema and tension pneumothorax, both of which were decompressed immediately by performance of water-sealed intercostal catheter drainage.

During the evening of the third postoperative day the patient's condition became critical. Peripheral pulses could not be felt; the heart rate was 200 per minute. He was extremely cyanotic and was struggling desperately for air with his remaining physical power. The patient was placed in a Drinker respirator and 15 mg. of tubocurarine chloride was administered intravenously. All voluntary muscular activity ceased immediately, and the patient was given artificial respiration. Within an hour the cyanosis completely disappeared, the pulse rate slowed to 120 per minute, and the blood pressure rose to 90/60 mm. Hg. Small doses of curare were administered intravenously whenever the patient showed voluntary muscular activity. The next morning his blood pressure was 110/80 mm. Hg, with the pulse rate 105 per minute. He had no further attacks of pulmonary edema and his color remained good.

The patient was kept completely paralyzed by administration of curare, and artificial respiration was given for 48 hours. Thereafter the dosage of curare was gradually decreased. The patient remained well accommodated to the breathing rhythm *of the machine.* The next day he was removed from the respirator. His breathing was then assisted by a Bennett machine for an additional four days. His condition remained satisfactory; he had no dyspnea or cyanosis at rest and left the hospital on the 30th postoperative day in good condition. The patient has been closely observed since discharge. He has remained well compensated.

Summary

A 10-year-old boy underwent open cardiotomy because of a large interatrial septal defect, with pulmonary hypertension and bidirectional shunt. The patient developed acute cardiorespiratory insufficiency on the third postoperative day.

Despite active therapeutic management his condition became critical. To relieve the patient of his extremely severe dyspnea and provide adequate gas exchange, he was placed in a respirator and complete musculoplegia was induced by prolonged administration of curare. The patient improved rapidly. He was kept in a respirator while curare was administered for a period of 48 hours, after which he showed satisfactory recovery.

TONS OF PESTICIDES.—The use of parathion as an insecticide started during the second world war. It was first sold in Finland in 1950 and by 1957 the total of parathion preparations sold had risen to 160 tons. Nearly two-thirds of all pest extermination on farm and garden now employs pesticides containing parathion. . . .

To obtain an idea of the significance of the number of fatal cases due to parathion pesticides, we can mention by way of example that in Finland pregnancy, parturition, and puerperal complications were the cause of death of 94 persons in 1955, 99 in 1956, and 77 in 1957. Again, deaths from poliomyelitis in 1956, when mortality from this disease was at its highest, were 37. . . . In Finland between 1952 and 1957 there were 286 deaths from parathion pesticides used in agriculture and horticulture. In 1957 the number had risen to 105; 237 of the total deaths were by suicide. Only 20% of these cases had an opportunity of procuring the poison for their work. The sale of parathion preparations should be more strictly controlled.—T. Toivonen, M.D., K. Ohela, M.D., W. J. Kaipainen, M.D., Parathion Poisoning Increasing Frequency in Finland, *The Lancet,* Aug. 22, 1959.

COUNCIL ON DRUGS

Report to the Council

The Council has authorized publication of the following report.

H. D. Kautz, M.D., *Secretary.*

CURRENT STATUS OF THERAPY OF BRUCELLOSIS IN HUMAN BEINGS

Wesley W. Spink, M.D., Minneapolis

The successful management of brucellosis in human beings depends on a recognition of certain basic features of the disease. Brucellosis is caused by one of three species of brucellae, namely, Brucella abortus, Brucella melitensis, and Brucella suis. This distinction is important because the natural course of the disease differs in severity according to the species of brucellae that has invaded the tissues. Illness caused by Br. abortus is less severe than that caused by the other two species. This form of brucellosis is most prevalent in the United States. Disease resulting from Br. melitensis is more serious and is characterized by prostration, complications, and chronicity. Br. melitensis is the cause of most brucellosis in human beings, worldwide. The outstanding feature of brucellosis due to Br. suis is a debilitating and prolonged febrile illness, with complicating suppurating lesions of the bone and viscera. Brucellosis caused by Br. suis is prevalent in certain areas in the United States where large numbers of swine are raised.

Another basic factor in the management of brucellosis is the necessity for establishing a precise diagnosis of active disease before starting therapy. This requires careful bacteriological and serologic studies. When infection cannot be established bacteriologically by culture, the results of brucella sero-agglutination tests must be cautiously interpreted. In general, agglutination titers of 1:100 or over are consistent with active disease. Lower titers are often of doubtful significance, especially when these low titers are found with repeated tests. When bacteriological cultures remain sterile and brucella agglutinins are absent or present only in a low titer, a positive intradermal brucella test is of doubtful diagnostic value. The brucella skin test is specific and indicates past exposure to the disease, but a positive test does not connote active brucellosis.

One added feature of brucellosis requires elucidation. Brucellosis may have a severe impact on the nervous system. Weakness and mental depression are common manifestations. An emotionally unstable person may be plunged into a severe depression after an acute brucella infection. He may be mistakenly subjected to "antibrucella therapy" for several years instead of having efforts directed toward correcting the underlying psychosomatic disturbance. On the other hand, it is also a grave error to subject a patient with undetected active brucellosis to psychotherapy. The correlation of neurological and psychic disturbances with brucellosis should be kept in mind.

After the diagnosis of active brucellosis has been established, the patient should be informed that brucellosis is a self-limited disease. The patient is not encouraged when he is told that brucellosis can result in a chronic debilitating illness; however, brucellosis causes disabling chronic illness in relatively few patients. The emotional pattern of the patient must be carefully surveyed, since his ultimate restoration to good health will often depend on this factor. For the most part, brucellosis is an occupational disease, and the interpretation of chronic illness can be the result of disability insurance.

Specific Measures

The patient with active brucellosis should engage in a minimum of physical activity. The toxic and febrile patient should be kept in bed. Somatic pains and headaches can be alleviated with salicylates, although the nocturnal sweats associated with brucellosis can be accentuated by therapy with salicylates. Insomnia and nervousness during the acute illness can be relieved with sedatives.

It has been established in experimental brucellosis and in man that antibiotics will suppress the infection, reduce complications, and shorten the course of the disease. The tetracycline drugs, chlortetracycline (Aureomycin) hydrochloride, oxytetracycline (Terramycin) hydrochloride, or tetracycline (Achromycin, Panmycin, Polycycline, Steclin, Tetracyn) hydrochloride, constitute the treatment of choice and are recommended in an oral dose of 500 mg. every six hours for a minimum of 21 days. If the patients tolerate the drug well, this same

---

From the Department of Medicine, University of Minnesota Medical School.

therapeutic regimen can be repeated within six to eight weeks, if a relapse should occur. It is not unusual for patients to have a relapse of their illness two to three weeks after the completion of an initial course of tetracycline therapy, especially with disease caused by Br. melitensis. In the more severe cases, 1 to 2 Gm. of streptomycin daily for 14 days should be simultaneously administered intramuscularly. In some instances, the disease may relapse two and three times before recovery takes place. One of the tetracyclines should be used for 21 days for each relapse. It is very doubtful if more than three courses of antibiotic therapy are beneficial, except in the rare patient in whom demonstrable suppuration is present.

Patients exhibiting a severe toxic state may have an accentuation of their illness shortly after an initial dose of antibiotic. This systemic reaction can be so severe that peripheral vascular collapse occurs. This unfavorable reaction is presumed to be due to the antibrucella action of the drug liberating brucella antigen (endotoxin) in a patient with acquired brucella hypersensitivity. This reaction can be prevented by administering corticotropin (Acth, Acthar, Corticotropin) or one of the glucocorticoids with the antibiotic. A suspension of corticotropin can be given intramuscularly in a dose of 40 mg. every eight hours. Cortisone (Cortisone, Cortogen, Cortone) acetate is given orally in a dose of 100 to 300 mg. three times daily or prednisone (Deltasone, Deltra, Meticorten, Paracort) in an oral dose of 20 mg. three times daily. Steroid therapy also is beneficial in the seriously ill patient. The initial Herxheimer-like reactions can also be avoided by use of small initial doses of antibiotics. The toxemia and febrile state gradually subside over a period of several days when antibiotics alone are used, but, when steroid drugs are also employed, the patient improves within 24 hours. Treatment with steroids should not be continued for more than 72 hours and should be restricted to the more seriously ill patients.

Although brucella vaccines are used for brucellosis in human beings, there is no general agreement concerning their value. Vaccine has usually been employed in the treatment of chronic brucellosis. The attempt is made to desensitize patients to brucella antigen by intermittent parenteral injections of the material over a long period of time. Unfortunately, the results are difficult to evaluate, and the vaccines cause considerable discomfort and expense to the patient. Vaccine has also been recommended for the more acutely ill patients, along with antibiotics. The vaccine is given intravenously in a dose that will provoke a systemic febrile reaction. This procedure is dangerous since peripheral vascular failure can occur. Until more definitive evidence is at hand, vaccine therapy cannot be recommended for either "desensitizing" purposes or for the purposes of inducing a pyrogenic response.

Chronic Brucellosis

One of the problems that perplexes clinicians is the management of patients with so-called chronic brucellosis. These persons express subjective complaints consistent with chronic illness, but objective evidence of disease is often not apparent. Lacking either bacteriological or significant serologic proof of activity, these patients are not infrequently subjected to long courses of vaccine therapy. They usually have a positive dermal reaction for brucella antigen. In addition to vaccine, they may also receive one or more courses of antibiotic therapy. The precise diagnosis is usually in doubt, and the results of therapy may be dubious.

Comment

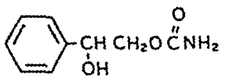
At present, neither vaccine nor antibiotic therapy can be recommended for acute or chronic illness unless the diagnosis of brucellosis can be supported by dependable bacteriological or serologic data. Subjective complaints, with or without a positive brucella skin test, do not constitute sufficient evidence for a diagnosis of active brucellosis.

NEW AND NONOFFICIAL DRUGS

The following descriptions of drugs are based on available evidence and do not in any case imply endorsement by the Council.

H. D. Kautz, M.D., *Secretary*.

Styramate (Sinaxar).—2-Hydroxy-2-phenylethyl carbamate.—The structural formula of styramate may be represented as follows:



Actions and Uses.—Styramate displays a pattern of pharmacological activity in animals similar to that of mephenesin and other centrally acting skeletal muscle relaxants. Thus, experimental observations indicate that it is a central nervous system depressant with relative specificity in depressing polysynaptic spinal reflexes; it antagonizes convulsions induced either by drugs or by electroshock. After oral administration, the duration of action of styramate seems to be two or three times that of mephenesin. In animals, toxic doses produce decreased motor activity, ataxia, loss of the righting reflex, and paralysis. Chronic toxicity studies have revealed no adverse effects on the liver, kidney, or blood-forming tissues.

Of the reported clinical trials of styramate, few have incorporated comparisons with other muscle relaxants or with placebos. The present assessment of the efficacy of the drug must, therefore, be regarded as tentative. However, although much more experience or more carefully designed clinical investigation will be required to establish the value of styramate, the limited available evidence indicates that it may be helpful in relieving muscle spasm associated with a variety of clinical conditions, including myositis, fibrositis, arthritis, spondylitis, acute lumbosacral strain, and torticollis. It should be considered an adjunct to physiotherapy and other appropriate measures. The drug is not claimed to be effective in paralysis agitans.

Although drowsiness, vertigo, headache, and urticarial eruption have been reported after administration of styramate, the incidence of these side-effects was low, and their occurrence cannot be definitely ascribed to the use of the drug. Patients should be cautioned concerning a possible sedative effect, however.

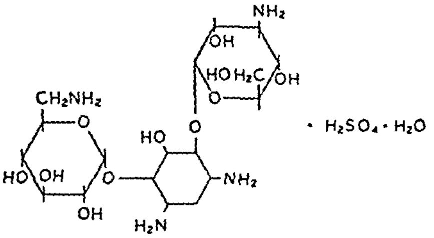
Dosage.—Styramate is administered orally. The dose is adjusted in accordance with the needs and tolerance of the individual patient. Although larger doses have been used, 200 mg. four times daily should be tried initially. If the response is unsatisfactory, the dose may be gradually increased, as required, until a total daily dosage of 1.6 Gm. is reached, unless untoward effects supervene.

Preparations.—tablets 200 mg.

Year of introduction: 1958.

Armour Pharmaceutical Company, Division of Armour and Company, cooperated by furnishing scientific data to aid in the evaluation of styramate.

Kanamycin Sulfate (Kantrex).—The sulfate salt of an antibiotic substance derived from strains of Streptomyces kanamyceticus.—Kanamycin is a thermostable, water-soluble, polybasic substance. Its chemical structure consists of two amino sugars glycosidically linked to deoxystreptamine. The chemical structure of kanamycin sulfate may be represented as follows:



Actions and Uses.—The in vitro antibacterial activity of kanamycin is almost identical with that of neomycin. Kanamycin is active against many aerobic gram-positive and gram-negative bacteria, including most of the strains of staphylococci so far isolated from clinical sources. Gram-negative organisms sensitive to kanamycin include species of Klebsiella, Aerobacter, Shigella, Salmonella, Neisseria, Escherichia coli, and the majority of strains of Proteus. It is active against mycobacteria. Common gram-positive pathogens such as streptococci and pneumococci are usually resistant to kanamycin at concentrations attainable in body fluids. Enterococci, Brucella, and Pseudomonas organisms are generally resistant as are clostridia, bacteroides, yeasts, and fungi. It is recommended that clinical therapy with kanamycin be guided by in vitro antibiotic sensitivity tests whenever possible.

The development of bacterial resistance to kanamycin can be demonstrated in vitro and in vivo against most sensitive organisms so far tested. There is almost complete cross resistance of organisms to neomycin and kanamycin and one-way cross resistance between streptomycin and kanamycin; i. e., organisms made resistant to kanamycin are resistant to streptomycin, but organisms made resistant to streptomycin are sensitive to kanamycin. In the case of the mycobacteria, cross resistance does not exist between kanamycin and streptomycin. Mycobacteria exhibit similar one-way cross resistance between viomycin and kanamycin. Kanamycin probably is bactericidal against most of the sensitive organisms; it is more active under aerobic than anaerobic conditions. The mechanism of action has not been fully elucidated. Against mycobacteria, kanamycin is bacteriostatic rather than bactericidal; mycobacteria develop resistance as rapidly as with streptomycin. Bacterial resistance can be induced among sensitive staphylococci, but it occurs in a slow, step-wise fashion as is the case with penicillin.

Kanamycin is absorbed rapidly from intramuscular sites but only slightly absorbed from the gastrointestinal tract. Hence, kanamycin must be used parenterally for systemic infections. After intramuscular injection, the drug is absorbed rapidly, inducing peak serum concentrations within one hour after injection. Blood levels from recommended doses are maintained for 8 to 12 hours. Kanamycin does not cross the blood-brain barrier in persons without meningeal infection at doses so far used, but it may reach significant concentration if the meninges are inflamed. Kanamycin appears in pleural, peritoneal, and synovial fluids after intramuscular injection.

Kanamycin is not recommended in minor or self-limited infections and should be used cautiously in the presence of renal impairment because of the increased risk of ototoxicity in such patients; in moderately severe or severe infections which are about equally susceptible to more than one antimicrobial agent, including kanamycin, the choice of therapy should be determined on the basis of relative potentiality for inducing serious toxic effects. Because of the lack of cross resistance between kanamycin, penicillin, streptomycin, chloramphenicol, novobiocin, oleandomycin, and the tetracyclines, kanamycin may be useful in infections which have failed to respond to those antibiotics. There appears to be no doubt that kanamycin has been lifesaving in those instances in which organismal resistance precludes the use of other antimicrobials.

Parenteral therapy with kanamycin has been successfully used in patients with staphylococcic and gram-negative infections of the respiratory tract, soft tissues, and the urinary tract as well as in osteomyelitis, septicemia, and bacteremia. Kanamycin may be given orally for infections of the gastrointestinal tract due to sensitive organisms, particularly Salmonella and Shigella; severe infections may require supplemental parenteral therapy. Kanamycin may be used for preoperative preparation of the large intestine in the same manner as neomycin. It has also been used orally to destroy nitrogen-producing bacteria as a means of reducing blood ammonia levels in cirrhotic patients suffering from hepatic coma. Limited clinical experience indicates that kanamycin given orally may be effective in eliminating cysts of Entamoeba histolytica from the stools of asymptomatic carriers.

Kanamycin has been given in a 2.5% concentration by intraperitoneal instillation after exploration for established peritonitis or after contamination due to fecal spill during surgery. The usefulness of this procedure is not established because of the danger of respiratory paralysis when the patient is still under the effects of anesthetics or muscle relaxants and because of the possibility of renal damage if the patient goes into shock. The drug has also been used as an irrigating solution (0.25%) in abscess cavities, in the pleural space, and in the peritoneal and ventricular cavities.

Kanamycin is not now recommended for the treatment of tuberculosis. However, clinical investigation programs are in progress, which should point out the proper place of kanamycin in therapy of tuberculosis.

Limited clinical studies indicate that kanamycin is effective in cutaneous anthrax and in acute gonorrhea in the male, but it is not recommended for these infections because less toxic antimicrobials are equally effective.

Toxicity and Side-Effects.—The major toxic effect of parenterally administered kanamycin is its action on the auditory portion of the eighth nerve. This effect seems to be related to the height and duration of serum concentrations of kanamycin. For this reason, the recommended daily dose of 15 mg. per kilogram of body weight should not be exceeded except in rare instances, nor should the duration of therapy be prolonged unnecessarily. Ototoxic reactions are much less frequent in well-hydrated patients under 45 years of age with normal kidney function who receive less than 20 Gm. of kanamycin in 10 to 14 days and who have not previously received streptomycin, dihydrostreptomycin, or neomycin. The drug should be used with extreme caution and in considerably reduced dosage in patients with impaired renal function, since delayed excretion of the drug induces unnecessarily high serum levels and sharply increases the risk of ototoxicity. The risk of ototoxicity is also greater in patients beyond middle age. Deafness can be either partial or complete and, in most cases, has been irreversible.

Hearing loss is sometimes preceded by tinnitus or dizziness. If these symptoms occur, the drug should be withdrawn immediately. In patients with impaired renal function, hearing loss and even total deafness has occurred two to seven days after the drug has been withdrawn. This appears to be due to the maintenance of high serum levels because of failure of excretory mechanisms. If kanamycin is to be used in the treatment of infections in patients who have renal impairment, the daily dosage should be reduced by as much as one-quarter or one-half the total daily dosage. If possible, the patient's hearing should be checked with the audiometer before and during treatment, and kanamycin therapy should be stopped if there is loss of high frequency response.

Evidence of renal irritation (casts, albumin, and microscopic hematuria) frequently occurs during parenteral therapy with kanamycin. This seems to be associated with the rapid excretion of the drug by glomerular filtration and selective reabsorption of water (but not of kanamycin) in the tubules. These effects appear to be reversible on cessation of therapy and are not indications for withdrawing kanamycin if the patient's infection is responding. In some patients with concurrent renal failure, particularly those suffering from intercapillary glomerulosclerosis (Kimmelstiel-Wilson syndrome), kanamycin may be nephrotoxic. Increasing elevation of the blood urea nitrogen level or the appearance of oliguria are indications for stopping kanamycin therapy.

Some local irritation or pain may follow intramuscular injection, but this has rarely interfered with continued therapy. Eosinophilia has been noted. Among the minor side-effects to the drug are rare instances of sensitization, skin rash, drug fever, headache, and paresthesia. Neither hematopoietic nor hepatic toxicity has been noted, either in animal studies or during clinical use.

Because of its slight absorption from the gastrointestinal tract, oral administration is generally well tolerated and without significant side-effects. The possibility of absorption of kanamycin from ulcerated intestinal lesions or retention due to shock or renal damage should be borne in mind, but ototoxicity after oral administration is unlikely and has not been reported.

Dosage.—Kanamycin sulfate is given by intramuscular injection, but it also may be administered intravenously for systemic effect. For local or topical effect, kanamycin may be administered orally, intraperitoneally, by inhalation as an aerosol, and by intracavitary instillation. Dosage is expressed in terms of the free base. Patients receiving systemic kanamycin therapy should be well hydrated.

For intramuscular administration in adults and children, the daily dosage should not exceed 15 mg. per kilogram of body weight given in two or three divided doses. If infection is not controlled within five days, the clinical picture should be reevaluated.

The intravenous injection of kanamycin sulfate is recommended only for gravely ill patients with overwhelming infections or with impending vascular collapse. When indicated, a 0.25% solution (2.5 mg. per cubic centimeter) is prepared and administered by slow intravenous infusion at a rate of 3 to 4 cc. per minute. The dosage for adults and children is 15 to 30 mg. per kilogram of body weight per day given in two or three divided doses.

For intraperitoneal use after surgery in patients with peritonitis or fecal contamination of the peritoneum, 2.5% solutions (500 mg. of kanamycin in 20 cc. of water for injection) have been instilled through a polyethylene catheter sutured into the wound at closure.

For inhalation (aerosol) therapy in patients with respiratory tract infections, a solution containing 250 mg. in 1 cc. is diluted with 3 cc. of sodium chloride injection and nebulized.

For intracavitary use, a 0.25% irrigating solution (2.5 mg. per cubic centimeter) has been instilled in abscess cavities, pleural space, and peritoneal and ventricular cavities. Small amounts should be used: the volume given intrathecally or into the ventricles should probably not exceed 5 cc.

For preoperative preparation of the large intestine, kanamycin is given orally in doses of 1 Gm. every hour for four hours, then 1 Gm. every six hours for 36 to 72 hours before surgery. For oral use in the treatment of Shigella and Salmonella infections, total daily dosage has ranged from 15 to 30 mg. per kilogram of body weight. In amebiasis, oral dosage has ranged from 30 to 150 mg. per kilogram of body weight per day given in divided doses for 10 days.

It must be emphasized that kanamycin should be given orally only for the purpose of obtaining antibacterial effects within the intestine; it should not be given orally for systemic infections.

Preparations.—capsules 500 mg.; solution (injection) 500 mg. in 2 cc., 1 Gm. in 3 cc.

Bristol Laboratories Inc. cooperated by furnishing scientific data to aid in the evaluation of kanamycin sulfate.

Buccal and Intramuscular Use of Streptokinase-Streptodornase (Varidase)

The Council has reviewed the available evidence pertaining to the usefulness of buccally or intramuscularly administered streptokinase-streptodornase for the treatment of edema associated with inflammation or infection. (For a description of topical or intracavitary therapy with this enzyme preparation in the management of suppurative conditions in which infection or purulent exudation is present, see the monograph on streptokinase-streptodornase in New and Nonofficial Drugs.) It is postulated that the beneficial effects of buccally and intramuscularly administered streptokinase-streptodornase are due to the streptokinase component of the mixture and are explained by the ability of this enzyme to liquefy fibrin thrombi through activation of plasmin in blood and lymphatic channels and by lessening the viscosity of edema fluid. It is claimed that streptokinase permits easier access of the humoral forces of the host and concomitantly administered antibiotics to the area of infection. Although this may be theoretically plausible, the experimental observations in animals are incapable of establishing such a mode of action.

Among the conditions for which streptokinase-streptodornase may prove useful are those that may be associated with acute inflammatory processes, such as thrombophlebitis; cellulitis; abscess; sinusitis; arteriosclerotic, varicose, and stasis ulcers; hematoma; contusions; the congestion associated with bronchitis and bronchiectasis; sprains; fractures; dental surgical procedures, and any form of trauma. Clinical experience with buccally or intramuscularly administered streptokinase-streptodornase has been extensive, and many favorable results have been reported. Relief of pain, quicker resolution of edema, and more rapid subsidence of infection are said to follow its use. However, few of the studies have been well controlled. This seriously hampers a precise evaluation of the drug. Due to the variable course (with or without treatment) of the conditions for which streptokinase is proposed, it is difficult to assess, in the absence of carefully controlled studies, what part in the over-all improvement of the patient may be ascribed to the drug. In patients with edema associated with infection, streptokinase-streptodornase should be administered concomitantly with antibiotics. Comparative observations, with placebo medication substituted for the enzymes, would be difficult to carry out. However, in the absence of such studies, it is not possible to determine whether enzyme therapy was a contributing factor in the accelerated improvement of the patients. Clinical observations would tend to support the conclusion that the adjunctive use of streptokinase-streptodornase by either the buccal or intramuscular routes has a useful place in the management of inflammatory edema, with or without infection. The evidence presented to support this conclusion does not, however, withstand critical scrutiny. Accordingly, in the judgment of the Council, the usefulness of the drug by these routes of administration is unestablished.

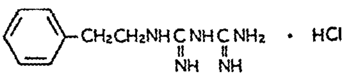
When administered by the buccal route, streptokinase-streptodornase is well tolerated. Side-effects have been limited to urticaria, skin rashes, and rare instances of local irritation and dryness at the site of tablet disintegration. When the drug is given intramuscularly, pain at the site of injection has been observed in many patients. Febrile reactions have also followed its parenteral injection; as with any parenterally administered foreign protein, there is a theoretical risk of serious allergic reactions. By either route, caution is advised when there is evidence of a defect in blood coagulation or impairment of liver function.

For buccal use, a tablet containing 10,000 units of streptokinase is placed in the buccal pouch or under the tongue and allowed to dissolve slowly. The usual dose is one tablet four times daily. The tablets should not be chewed or swallowed whole. For intramuscular use, a solution is prepared from the streptokinase-streptodornase mixture which provides 10,000 units of streptokinase per cubic centimeter. The proposed dose is 0.5 cc. (5,000 units of streptokinase) injected twice daily in the gluteal region. Although the evidence that streptokinase-streptodornase exerts a beneficial effect is inconclusive, the foregoing doses may be regarded as a base line or guide.

The Council voted to expand the monograph in New and Nonofficial Drugs to describe the buccal and intramuscular use of streptokinase-streptodornase, with caution as to the experimental status of these routes of administration.

Lederle Laboratories Division, American Cyanamid Company, cooperated by furnishing scientific data to aid in the evaluation of the buccal and intramuscular use of streptokinase-streptodornase.

Phenformin Hydrochloride (DBI).—N^1-β-Phenethylbiguanide hydrochloride.—The structural formula of phenformin hydrochloride may be represented as follows:



C_6H_5-$CH_2CH_2NH\overset{}{\underset{NH}{C}}NH\underset{NH}{C}NH_2 \cdot HCl$

Actions and Uses.—Phenformin hydrochloride is an orally effective hypoglycemic agent used in the management of diabetes mellitus. A biguanide derivative, it should not be confused with the distinctly different diguanidine compounds, some of which also have hypoglycemic activity but which may produce renal and hepatic damage. Nor is it related chemically to the sulfonylurea compounds, such as tolbutamide, or to insulin.

Phenformin hydrochloride may be used alone, in conjunction with insulin, or with other antidiabetic agents. It has a somewhat wider spectrum of usefulness than the sulfonylurea derivatives, but, like the latter, it is a much less potent hypoglycemic agent than is insulin; when used alone, it effects normoglycemia and eliminates glycosuria in only a portion of the patients in whom it is tried. The patients in whom it is most likely to be effective are those in whom the disease is stable, is of recent onset, began after the onset of maturity, requires only small doses of insulin, and has never been complicated by acidotic ketosis. In an additional group of patients whose symptoms cannot be satisfactorily controlled by administration of sulfonylurea or biguanide derivatives alone, the concomitant use of these two groups of oral agents may render supplemental insulin unnecessary. Finally, unlike the sulfonylurea compounds, it is also effective in a few cases of labile diabetes and of juvenile diabetes, although most patients in these groups will continue to require insulin.

Phenformin hydrochloride alone is only occasionally effective in diabetes requiring more than 40 units of insulin per day. It should not be used in diabetes that is controlled by diet alone, in juvenile diabetes that is well regulated by insulin, in the management of diabetes during the early postoperative period, and in such complications of diabetes as acidosis, coma, and infection. In stable diabetes, phenformin hydrochloride offers an advantage over insulin only when it is effective alone, since little is gained by a mere reduction in the dose of insulin. In unstable diabetes, on the other hand, the conjunctive use of phenformin hydrochloride and insulin may be justified, since the concomitant use of the two drugs sometimes effects smoother regulation than the use of either alone.

That phenformin hydrochloride lowers blood sugar level and eliminates glycosuria in many patients is undeniable; whether it corrects the underlying defects in carbohydrate, fat, and nitrogen metabolism, however, is still unknown. Thus, it is somewhat disturbing that some patients in whom phenformin hydrochloride maintains a normal blood sugar concentration may experience loss of weight, weakness, and lassitude unless small doses of insulin are also administered. Too, the effects of phenformin hydrochloride on the vascular and other long-term sequelae of diabetes can be determined only after years of experience. For these reasons, patients receiving this relatively new drug must be most attentively observed for both acute and long-term complications.

Phenformin hydrochloride, like other oral hypoglycemic agents and like insulin, controls rather than cures diabetes mellitus. It does not obviate the need for complete education of the patient concerning his disease and its treatment. The importance of adherence to a carefully formulated diet and of the prevention and treatment of diabetic complications must still be stressed. All patients must be instructed in the use and injection of insulin, since this drug remains the indispensable agent for the treatment of the acute complications of diabetes mellitus.

Side-Effects.—The usefulness of phenformin hydrochloride is limited by the frequency with which gastrointestinal symptoms such as anorexia, nausea, vomiting, and diarrhea occur. The incidence and severity of these symptoms are proportional to the dose. Although they occur in about 25% of patients receiving 150 mg. or more per day, an occasional patient may tolerate much larger doses. These and other minor side-effects are reversible and ordinarily disappear within 24 hours after the drug is withdrawn. Adverse effects on the liver, kidney, or hematopoietic tissues or other serious toxicity have not been reported.

Pharmacology.—In therapeutic doses, phenformin hydrochloride has few effects other than its hypoglycemic action. Adrenal function, as measured by 17-ketosteroid and 17-hydroxycorticoid urinary excretion, is not altered; response to adrenocorticotropic hormone remains unchanged. Nor does there appear to be any effect on thyroid function; although uptake of iodine by the thyroid may increase slightly in some patients, there is no alteration of serum protein-bound iodine or of cholesterol concentration. The blood concentrations of pyruvic acid and lactic acid may increase slightly in diabetic patients but usually remain unchanged when the drug is given to normal persons.

Phenformin hydrochloride is apparently absorbed satisfactorily from the gastrointestinal tract. Its time-action curve has not been described in detail in human beings, but experiments in animals suggest that it has a relatively brief duration of action, with the peak effect occurring three to five hours after administration of a single dose. The metabolic fate and routes of excretion of the drug are unknown.

Evidence concerning the mechanism of action of phenformin hydrochloride is conflicting. That insulin-secreting tissue is not necessary for its action is clear, since the drug lowers the blood sugar in depancreatized animals, although to a lesser degree than in the intact animal. The effect is also observed in the animal made diabetic by treatment with alloxan and in the hepatectomized animal. Phenformin hydrochloride does not lower the blood sugar level in nondiabetic man. The greater part of the present evidence suggests that its most important action is to increase the rate of anaerobic metabolism of glucose. There is some evidence that a decrease in gluconeogenesis and an increase in the oxidation of glucose via the hexose monophosphate shunt may also occur. Although phenformin hydrochloride, like many other drugs, inhibits the degradation of insulin in vitro, it seems unlikely that this action contributes significantly to its effects in vivo.

Dosage.—Phenformin hydrochloride is administered orally. As with any agent used in the management of diabetes, the dose must be adjusted to meet the needs of the individual patient. The drug may be given with meals in an attempt to minimize gastrointestinal side-effects, although there is no evidence that these effects are due to local irritation. Two or three doses a day will produce satisfactory results in many patients, but four doses a day will often afford smoother regulation of the blood sugar level. The dose should be low initially and increased gradually. Although there is no contraindication to the use of larger doses in patients who require and tolerate them, the incidence of gastrointestinal side-effects is quite high when the total daily dose exceeds 150 mg. It should be remembered that, with a given dosage schedule, significant hypoglycemic response may not be apparent until after a period of three days or more.

Hospitalization facilitates proper dosage adjustment. The effect on blood sugar level, urine sugar level, and ketone bodies must be carefully observed. Should signs of acidotic ketosis, impending coma, or other complications appear, the insulin dosage must be immediately increased and other appropriate therapeutic measures instituted.

In diabetics who have never received insulin, but in whom the disease cannot be satisfactorily controlled by diet alone, phenformin may be started in initial doses of 25 mg. twice daily. If the response is not satisfactory, the daily dose is increased by increments of 25 mg. at intervals of three or four days.

In patients who are receiving insulin, the dose of phenformin hydrochloride is gradually increased as the dose of insulin is reduced. The dose of phenformin hydrochloride that will be needed cannot be predicted from the insulin requirement. In all cases, the initial dose of phenformin hydrochloride is 25 mg. twice a day; again, the total daily dose is increased in increments of 25 mg. at intervals of three or more days, as required. In adults with stable diabetes, who require less than 30 units of insulin per day, the insulin may be withdrawn at once, or, if preferred, the dose may be reduced gradually; if the daily insulin requirement exceeds 30 units per day, however, the insulin dose should not be reduced by more than 25% at one time.

In labile or juvenile diabetes, usual doses of insulin are continued for several days after treatment is begun. The dose of insulin is then reduced very slowly; each reduction should not exceed 10%. In these cases, complete withdrawal of insulin is ordinarily impossible, so that the usual objective is smoother regulation than is possible with the use of insulin alone.

Preparations.—tablets 25 mg.

Year of introduction: 1959.

THE CHEMISTRY OF ANTIBIOTICS

THE chemotherapeutic properties of penicillin which were revealed by serendipity, followed by the discovery of streptomycin after years of critical investigation, appeared to be remotely related areas in microbiology. During the past decade the tremendous volume of research that has been pursued throughout the world in gathering additional information as well as the identification of new compounds which resulted in the synthesis recently of penicillin has unfolded a fascinating plan of biological action and cellular metabolism. The trail of investigative efforts led not only to the development of antibiotics such as chloramphenicol, the tetracyclines, and erythromycin but also to the revelation of compounds that are effective against infection by selected fungi. There is yet another column in the rapidly changing kaleidoscope that may be equally significant. The selective inhibition of the growth of tumor cells or viruses that contribute to the metaplasia of cells has resulted in no immediate therapeutic possibilities, but the long-term results in this endeavor may be critical for the understanding of the pathogenesis of malignant life.

Investigations into the microbiology of the actinomycetes, a filamentous bacteria isolated from the soil, which may produce actinomycosis, lumpy jaw in man and animals, have been particularly promising. It is a strange phenomenon that some parasites attack other parasites and also that suppression of some types of infection enhances the growth of others and permits the emergence of antibiotic-resistant strains. Were it not for this second action, investigations into the microbiology of antibiotics might well be progressing at a much slower pace. Furthermore, if the discoveries of the first decade of the antibiotic era had produced maximally effective agents without such serious handicaps, specific studies that concern cellular metabolism as noted below might not have been pursued.

Although the antibiotics embrace a wide variety of compounds, there is selective relationship structurally among the several groups. Penicillium chrysogenum is capable of synthesizing a number of penicillins which differ in the side chain only, depending on the precursor of the side chain that was added to the culture medium. Streptomyces griseus produces streptomycin; other species of Streptomyces are responsible for the tetracyclines, such as aureomycin and terramycin. It is interesting to recount that the micro-organisms produce numerous variations on the basis of definite structural patterns and in spite of major differences in the end-products, items that are therapeutically effective, the building stones are relatively simple structures such as amino acid, acetate, and the sugars. Many of the antibiotics produced from bacteria or actinomyces that have been identified are polypeptides derived from amino acids through a different process of biosynthesis than the peptides and protein in animals.

Considerable progress may be recorded also in the understanding of the mechanism of antibiotic action. The pathogenesis of the chemotherapeutic effect varies from one substance to another, with one fundamental action manifest, i. e., the compounds are more toxic to micro-organisms than they are to animal tissues. There is a difference in selective toxicity, while minor changes in the molecule may result in significant change or even loss of therapeutic activity.

The style of cellular processes, nevertheless, is grouped into a limited number of categories, some of which are in process of definition. Considerable progress has been made in understanding the fragile membrane which surrounds the cytoplasm of gram-positive bacteria which is able to withstand a high internal osmotic pressure supported by a rigid cell wall. When certain organisms are exposed to the lysozyme enzyme, the walls dissolve, and the resultant spherical bodies burst when the external osmotic pressure is reduced by dilution with water. When viewed with the electron microscope, they appear as skins that have collapsed. Penicillin and bacitracin interfere with the growth of bacterial cell walls and thereby exert their antibiotic activity. The lack of toxicity for animal cells of penicillin is appreciated because such cells synthesize structures that are chemically unrelated to the substance of the walls of bacteria. Penicillin does not kill or lyse bacteria unless they are growing, and it is not until the cell begins to grow that its existing cell wall fails. A number of antibiotics employed in the practice of medicine are endowed with no lytic action on pathogenic bacteria, and the damage produced is different from that brought about by penicillin. Nor has the microbiological action of

---

1. Abraham, E.P.: Antibiotics in Microbiology, Endeavor 18:212, 1959.

streptomycin been elucidated. The broad-spectrum antibiotics, including chloramphenicol and tetracycline, are inhibitors of the synthesis of bacterial proteins.

The understanding of sensitivity and the development of resistance to antibiotics have progressed further in the penicillin-Staphylococcus struggle. The capacity of bacteria to acquire resistance is an example of adaptivity of microbiological life and relates to the basic problems of synthesis of proteins and nucleic acid. A number of bacteria are capable of elaborating the enzyme penicillinase that produces rapid hydrolysis in penicillin. High on the list are rapid strains of staphylococci. These survive; other strains are destroyed. The ability to synthesize the enzyme appears to depend on a specific genetic feature. The enzyme occurs naturally in some organisms; in others its formation can be induced. The rate of synthesis in the second category of bacteria is enhanced by the presence of penicillin.

It is obvious that a great deal of the mystery regarding the origin and chemical structure of the antibiotics has been exposed in recent years.[1] It is inevitable, however, that one hark back to the statement made by Fuller Albright a number of years ago: "A great deal of progress has been made, a great deal of investigation remains for the future."

SCIENCE, WHAT TWISTS THE COMET'S TAIL?

Chicago was fortunate during the holidays in having held within its halls the 126th annual meeting of the American Association for the Advancement of Science. For several days the parent organization, together with 103 of its affiliated societies, revealed such quantities of scientific information—facts, hypotheses, ideas, and opinions—that the intellectual climate of the Midwest can never be the same. About 6,000 scientists came from far and near to hear the communications, to inspect the exhibits, and to ask and answer questions.

Russell Lynes said in the *New York Times* book review section recently that in the last decade 3 billion books of all sorts have been bought by Americans and that "Science indeed scarcely showed its bright face on the best-seller lists at all." A speaker at the recent Chicago meeting estimated that if a person devoted every minute of his time in trying to keep informed of all published material during the year he would still be behind by more than 1.05 billion pages.

In this mountainous output of words, one group of scientists may borrow words from another. Biochemists have borrowed from industry the word "machines," which word was used during the Chicago meeting by a professor of enzyme chemistry when he stated that living systems contain a variety of cellular contrivances or machines which transform energy from one form to another. All known biochemical "machines" have a high degree of ordered structure within which special molecules actually do the energy transforming. The mitochondrion and the chloroplast are the two most fundamental biochemical machines of living systems. They are in effect the power plants of life. The mitochondrion burns sugar (in the form of pyruvic acid) to carbon dioxide and water and converts the energy released by oxidation to the stored energy of adenosine triphosphate (ATP). The chloroplast converts light energy into the bond energy of ATP by an analogous mechanism. Practically all biochemical machines are powered or triggered off by ATP, which in effect stands in the same relationship to cells as does electricity to our homes.

In a communication, "Steroid Hormones and Aging in Man," it was noted that the principal adrenal cortex hormone, hydrocortisone, and its metabolites are excreted in about the same amount in young as in elderly men and women. However, numerous studies have shown that, after the age of 20 years, a significant and steady decline in output of the 11-deoxy-17-ketosteroids occurs and that their relative deficit in aged persons may be responsible for such phenomena as weight loss, muscle wastage, and weakness.

Another speaker in the symposium on aging stated that the downward trend of employment of persons over 65 years of age continues and that today only one-third of all men and one-tenth of all women over 65 years of age are regularly employed. The median income of these employed older workers is $3,475 annually. But despite the weighting of these earnings, 40% of all older couples and 60% of all older single persons have incomes below minimum standards. The speaker suggested that a competent, high-level commission should be called together to advise government and industry on adequate, dependable, and coordinated methods of meeting the economic needs of older people.

A study of guests in an old people's home revealed that a wide variety of physiological functions show an apparent linear decrease between the ages of 30 and 90 years, the average varying widely for different functions tested under resting conditions. The rate of conduction of impulses in the ulnar nerve, for example, diminishes by 15% at the age of 30 years, whereas the blood flow through the kidney is reduced by 50% and the resting cardiac output by 30%. Studies of various renal functions indicated that with advancing age nephrons are lost as functioning units. Many other organ systems also showed varying degrees of functional impairment.

In this symposium on aging stress was defined, for practical purposes, as the consequence of the rate of "wear and tear" in a biological system, which system may be the organism as a whole (systemic stress) or one of its parts (topical stress). The visible manifestations of the former constitute the "general adaptation syndrome" while those of the latter are known as the "local adaptation syndrome." Both of these are triphasic reactions which evolve through an acute phase, the "alarm reaction," to the "stage of resistance" and finally end in the "stage of exhaustion." Stress is a general manifestation of any kind of vital activity (heartbeat, respiration, glandular secretion, or locomotion) which produces some "wear and tear." Hence, stress is not necessarily a pathological phenomenon, and complete freedom from it never occurs in living beings.

Among the exhibits at the Chicago meeting was a display of music and records of the space age intended to interest youngsters 6 years of age and older and give them some understanding of fundamentals. This was referred to as the "beep beep" school, and the six best-sellers among the records were "Constellation Jig," "Planet Minuet," "Ballad of Sir Isaac Newton," and "It's a Scientific Fact."

The president of the National Science Teachers Association believes that children in elementary schools today know much more science than we give them credit for and that they can learn throughout school much more science than we give them an opportunity to learn. Youngsters talented in science, he said, can be identified by the end of the sixth grade if science is well integrated into the curriculum for young children.

The retiring president of the AAAS, in his address at an evening session, said that by the overlapping expansion and growth of this nation's science programs a crisis has come about whereby none of the major programs can be adequately supported except at the expense of less glamorous areas of science, education, and culture. Even when stimulating conditions have been removed, the top priority label is often maintained; then another set of circumstances dictates the creation of another top priority label assignment to another area of science. He suggested "a liaison of government scientists with academic and industry scientists, to be represented by a national science council, in a manner compatible with the maintenance of our broad culture and balanced development."

A professor reported on a group of employed men beyond the age of 64 years, some of whom had retired and some of whom continued to work. The study was continued for several years, and, contrary to popular belief, no evidence was found that retirement affects health. The relation between the retirement and the death of a person a few months later was explained largely by the fact that persons in poor health tend to retire. On the other hand some evidence was found that retirement actually improved the health of some people. The speaker recommended that a person be permitted to work as long as he wants to do so and can measure up to an objective standard of accomplishment.

In a symposium on unsolved problems in biology, a professor of zoology described two classes of hereditary behavior. In most situations, he said, the parents make equal contributions to the traits of their offspring, and the numerical relations between the traits of the parents and those of the offspring are described fully by the classic Mendelian laws and their more recent extensions. Such heredity is governed by the behavior of the chromosomes in the nucleus of the cell. The other class of hereditary behavior is a conspicuous exception to the Mendelian rules. Instead of both parents, only the mother determines a particular trait in her offspring, and since this type of inheritance seems to be unrelated to the cell nucleus, it is assumed to be controlled by the cytoplasm, most of which, if not all, the mother contributes to the offspring. Such inheritance is called maternal or cytoplasmic inheritance. The existence of these two classes of hereditary behavior raises a fundamental question in genetics. If DNA, or a similar chemical compound, can be found in the cytoplasm specifically associated with the traits, we may be able to conclude that no fundamental difference exists between the two types of inheritance. However, if no relation can be established between DNA and cytoplasmically controlled traits, we must conclude that hereditary information can be stored and transmitted in other ways. Several possibilities concerning the supplementary mechanisms of storage can be suggested, but the facts required for a full interpretation are not yet available.

Studies in recent years have revealed that cytolysis is not restricted to human cancer cells and to human serums but that it can be reproduced in experimental ascites tumor cells and by various animal serums. At this meeting a group of investigators reported on experiments, mainly in vitro, on the possibility of cytolysis of tumor cells under the influence of soaps. Different ascites tumor cells and such non-neoplastic cells as erythrocytes, mammalian liver cells, and thymus lymphocytes were studied with respect to their sensitivity to cytolysis by the sodium salts of different saturated monobasic fatty acids. The investigators reported that fatty acids with a chain shorter than nine carbons do not destroy the mammalian liver cells and erythrocytes but attain a cytolytic effect on strongly proliferating cells, such as thymus lymphocytes and malignant cells. The strong cytolytic potency of the high molecular fatty acids is caused by the higher predominance of their nonpolar lipophilic part.

A mathematician, an automation expert, delivered an address entitled "The Nature of Social Dangers of the Controlled Machines of the Future." Obviously he talked about a different kind of "machine" from that mentioned in a previous paragraph. It is erroneous to assume, he said, that machines cannot possess any degree of originality. On the basis of such an assumption, many people pooh-pooh the dangers of thinking machine techniques, one of which is that they are able to act so quickly. Even when they do not transcend human intelligence in any way, they very well may, and do, transcend men in the performance of their tasks. By the very slowness of human activities, our effective control of our machines may be nullified. If such machines become more and more efficient and operate at a higher psychological level, the dominance of the machine becomes nearer and nearer.

An astronomer reported that radio signals picked up from the planet Jupiter in recent months indicate the presence of a magnetic field in space about 100 times stronger than the well known Van Allen belt around the earth. He also reported that the radiotelescope provides information indicating that the surface temperature on the planet Venus is about 585 degrees F. It is unlikely that liquid water exists anywhere on the surface of Venus. It is unlikely also that life exists on this planet.

Two university scientists, one a physicist and the other an astronomer, expressed opposing opinions about the forces that twist a comet's tail. The physicist theorized that a ring of flaming gas surrounding the sun generates a solar wind because of its 2 million degree heat and that the solar wind strikes the comet's tail and deflects it. Since comet tails contain little mass, comparatively small forces would be required to change their angle to the comet heads. The astronomer maintained that only small quantities of gas leak from the surface of the sun, except in case of great disturbances like solar flares, and that large quantities of gas (the solar wind) would be prevented by the sun's magnetic field from escaping from the sun.

From the best of vantage points, one could noc wholly scan the tremendous annual output from so many scientific societies. However, from a restricted view of a few programs one can safely say (1) that scientists today hold diverging opinions on many important problems and that only continuous intensive study will reduce the number (young people who contemplate scientific careers, therefore, should have no fear of having new worlds to conquer) and (2) that the electron microscope has so broadened and deepened what formerly could not be observed as to amount to a revolution in the biological sciences.

As we enter the space age the number of unsolved problems in science will increase. There will be many problems that need more immediate attention, with possible practical results, but there will be few in outer space of more interest to everyone than that of finding out what twists the comet's tail.

DESERT MEDICINE

The practice of medicine 50 years ago in the rugged, sparsely settled desert of the Southwest has been described vividly by one who was there.[1] Joseph H. Peck migrated to western Utah after graduation from Ensworth Medical College, St. Joseph, Mo. He plied his skill in a desolate land under as extenuating and primitive conditions as demanded in any area of the United States. The Western Pacific Railroad had been completed between Salt Lake City and California some years earlier. A spur was being laid south from Westover on the Utah-Nevada state line. This bordered the Great Salt Lake Desert to service a newly developed copper mining area in the Deep Creek Mountains. The Bonneville Salt flats were nearby. These flats, which have become famous in recent years as a speedway, are completely incapable of supporting flora or fauna.

The practice of medicine in the early days in this frontier land should be described and documented by those who can tell the story from firsthand experience i:: as delightful a style as Doctor Peck. A considerable revival of interest in preserving much of the "Old West," particularly of politics, mining, and railroading, may be recorded in recent years, quite unrelated to adult westerns. Medicine has received less than its proportionate share of interest during the recreation of communities such as Virginia City, Nevada, Ouray, and Leadville, Colo., and the failure to abandon the last spur of narrow gauge railroad that originates in Durango, Colo. These are four historical items that have as much to command attention as the Strip in Las Vegas, an example of a 1960 frontier community, or Monticello, Utah, a center for those on the quest of uranium deposits.

Two incidents in the small volume on Peck reflect the change in living over the years. The imposition of quarantine of a home stricken with scarlet fever will be recalled by the physicians who began practice before World War I. At that time no one except the physician was allowed to enter the quarantined home. Everything that was allowed to cross the threshold was either eaten, burned, or fumigated with sulphur candles before the quarantine was lifted. Another narrative concerned Eddie Rickenbacker, a many-faceted pioneer in American transportation on land and in the air. As a young man, Mr. Rickenbacker held several international automobile records prior to joining the Lafayette Escadril in World War I. On one occasion he became mired in the mud and sand in western Utah while attempting to establish a new transcontinental record by automobile. The extraction of the racing car is delightfully told by the author.

The author of "What Next" began his career of writing, at the age of 60 years, after retirement from medical practice. This latest effort is a notable contribution to documentation of frontier days in the great southwestern desert, a formidable barrier for most of the overland migration prior to the completion of the transcontinental railroad. Dr. Peck's efforts may serve as an incentive to other physicians who have experiences to relate and whose capacity to tell a story should be exploited. It is hoped that the number of medical novelists will be expanded and be productive before the experiences are lost forever.

---

DEPARTMENT OF INVESTIGATION

NEW CELLS FOR OLD

FOR "WELL-HEELED" OLDSTERS

Popular magazines recently have published many articles on the subject of health and disease. Occasionally the editors of certain magazines publicize an unestablished remedy, which brings it to the attention of the public as a medical discovery of alleged value in one or more disease categories.

Such an item has appeared in *Coronet*, a popular pocket-sized magazine; it covered the methods and claims of Dr. Paul Niehans, a Swiss physician. The editors noted that "Cellular therapy is a startling European treatment for old age and a wide variety of diseases. Because this medical technique is controversial and still unproven, *Coronet* asked Dr. Herbert S. Benjamin, an American physician and medical researcher, to discuss it with its discoverer, Dr. Paul Niehans of Switzerland, and to observe his work and evaluate the use of cellular therapy by many physicians in Western Europe . . ."

Dr. Paul Niehans has had the benefit of other items of publicity written on his behalf. The greatest flurry of such press-agentry occurred when he was called to treat the late Pope Pius XII in February, 1954. Among others who are alleged to have received his attention are Konrad Adenauer and W. Somerset Maugham.

The late Pope was suffering from a gastric disorder, the exact nature of which was never clearly described but which apparently involved a distressing bout with hiccoughs. The late Holy Father had at least one other physician in attendance, one Professor Galeazzi-Lisi, who later became involved with the Italian medical fraternity by selling photographs and an account of the late Pope's dying hours.

There is no clear indication, either, in all of the publicity which attended the nonfatal papal illness, whether or not fresh cell therapy, or royal jelly (another publicized rejuvenator), or the passage of time was responsible for his recovery. The Chicago *Tribune*, however, on June 3, 1957, in an Associated Press release bearing a Rome date line, reported that Dr. Niehans had written a book entitled "Niehans, Doctor of the Pope." Niehans was described in that news dispatch as having credited potato soup with being the effective therapeutic agent.

Beyond other newspaper publicity, Dr. Niehans has had the benefit of several magazine articles. A magazine called *Top Secret*, which was not dated, but was purchased in August, 1954, had an item entitled "Modern Miracle in the Vatican: The Controversial Doctor Who Saved the Pope's Life!" For some reason, however, this item did not reveal the use of potato soup. This account of the treatment was as follows:

> In February 1954, the world was confronted with a miracle in the great tradition of the Church. But it was a modern miracle in which twentieth century science cooperated with religion. In the recovery of the saintly Pontiff, his own abiding faith was aided by the skill of a physician who is a mystery man among the great doctors of the world. *Top Secret* can now reveal exclusively that the Pope's life, at what seemed to be the eleventh hour, was saved by the intervention of a 72-year-old Swiss physician named Dr. Paul Niehans. . . .
>
> Dr. Niehans is a controversial figure in the world of international medicine. He is a surgeon and, in five decades of practice, has performed thousands of operations and written twenty books on surgery. Yet surgery is his last resort. . . .
>
> Niehans then applied to the Pope his own special methods of treatment, known as cellular therapy. This unorthodox method consists in the transplantation of living cells from a freshly slaughtered animal.
>
> And in conjunction with this, a new miracle drug called "xylocaina," used to alleviate pain resulting from abdominal surgery, was given to the Pope. This drug was developed by Dr. Niehans in his own laboratories in Switzerland. . . ."

The Dec. 10, 1957, issue of *Look* magazine carried an item entitled "Is This Man Keeping the Pope Alive?" Reference was made to the use of cell therapy.

Mention of Dr. Niehans has also been made in *Time*. The Sept. 13, 1954, issue, in an item entitled "Help From Animal Cells?", referred to the use of glands and organs of animals being utilized by Dr. Niehans as long ago as 1931 and reported his reading of a paper before some physicians in Karlsruhe, Germany. This item included the following statement.

> Several doctors who have adopted the Niehans technique, giving injections of embryonic animal cells at costs ranging from $3.50 to $20, supported his claims. But others shook their heads. There are great dangers: allergic reactions, shock, accidental infection with viruses or other microbes. There is a good chance that the "placebo effect" (i. e., mental suggestion) is responsible for improvement in many patients.

Another issue of the same publication (*Time*, Aug. 31, 1959) contained an item concerning Dr. Niehans, entitled "The Healing Lamb."

The 1954 publicity prompted an inquiry from the Department of Investigation to the Swiss Medical Institutions at Bern. Following is the response received from the secretary:

> Dr. Paul Niehans, domiciliated at Clarens, uses to make injections of fresh organ's pap, to what he attributes an effect on the corresponding organ. This way of treatment is

> at the utmost specialized, as he injects, for instance, a substance of the interbrain against insomnia. The idea is at least 100 years old and the treatment with organ's dialysates has been tried several times. However, a sound scientific basis is not yet established. In Switzerland, Dr. Niehans did not succeed in gaining a great number of adepts, but it seems that this is more the case abroad.

Of interest, also, are the items critical of Niehans and his method. THE JOURNAL, (156:1348 [Dec. 4] 1954) under the heading Foreign Letters, carried an account of some untoward effects, including brucellosis and encephalomyelitis, developing in some patients treated with "fresh cells." This was described as having been reported by Professor Bennhold of the University of Tuebingen Medical School.

The European medical literature contains several references to the use of fresh cell therapy. One of these, entitled "Historical Development of Fresh Cell Therapy and its Application in General Practice", was published in the *München. med. Wchnschr.* for May 27, 1955 (Vol. 97, pp. 698-703). This discussed methods of administration, and suggested that the patient should be sleeping and should not awaken for at least 24 hours.

Another report, entitled "Fresh Cell Therapy: Critical Evaluation of Theory and the Nature of the Fresh Cell Therapy According to Niehans", by A. Pischinger, was published in the *Wiener medizinische Wochenschrift* (105:952-957 [Nov. 19] 1955). In this article Pischinger criticizes the Abderhalden serum test, which apparently is used by Niehans for diagnostic purposes. In addition to recalling harmful effects from the injection of fresh cells, including infections, it is stated that death has been traced to the treatment. This author questions the Niehans claim that fresh cell therapy is organ-specific, recounting his experience with animal experimentation, that no matter what organ source was injected, the biological effect was the same immediately after the injection.

Another critical report, entitled "Possibilities and Limitations of Cell Therapy," was published in the *Münchener medizinische Wochenschrift* (97:703-707 [May 27] 1959). The author, H. G. Rietschel, outlines three phases involved in cell therapy, the first being described as a hormone effect, the second as the stress stage (between the 11th and 14th day), and the last, one of regeneration. He points out that the likelihood is that cell therapy acts on the general cell metabolism but that specific effects, in the sense of a regenerative stimulation of a certain organ, have not been observed clinically.

There is reference to a patent granted in Switzerland in October, 1952, to Leo Schwander and Paul Niehans. This is a process of preservation of organ-cell preparations by freezing and sublimation. There is also a firm called Rhein-Chemie, Abteilung Dr. Niehans, in Heidelberg. In a promotional booklet called "Dr. Niehans Zellular-Therapie, Siccazell . . .", which, among other things, warns that cellular therapy is not a panacea and is contraindicated in all inflammatory diseases and in focal toxicoses, it is stated that there are certain diseases wherein the method is not successful. These include "amyotrophic lateral sclerosis, chondrodystrophy, lymphogranuloma, morbus Bechterew, Paget's disease, multiple sclerosis, myasthenia gravis pseudoparalytica, myatonia congenita, Parkinson's disease, postencephalitic conditions, scleroderma, syringomyeloma and all forms of leukemia."

The product is recommended in heart diseases, circulatory disturbances, arteriosclerotic changes and hypertension, climacteric, sterility, impotence, arthritis and rheumatism, mongolism, and prostatic diseases (including adenoma of the prostate). In the circumstances, such claims cannot be regarded as established. An attitude of scientific "Missourianism" will undoubtedly prevail in this country.

From European discussions and observations it is fair to say that the most favorable impression of the cell therapy is that it is experimental at best and does not provide, in the hands of others, what the originator claims for it. To an observer of some skepticism, however, this method of promotion brings a typical reaction, i. e., having failed to impress critical medical observers, the possessors of the particular treatment resort to the familiar methods designed to create a demand for a medical commodity.

On the other hand, THE JOURNAL (165:2133 [Dec. 21] 1957) carried an abstract of a report by G. Destunis entitled "The Treatment of Mental Deficiency and Encephalopathies in Childhood by Means of Fresh Tissue and Siccacell." This was from the *Archives of Pediatrics* and reported in part:

> In diencephalon implantations, a section of calf brain comprising the whole diencephalon and weighing approximately 20 Gm. is comminuted, and stirred into a mash to which is added 100,000 to 200,000 units of penicillin, and injected under pressure through a wide-bore cannula into the gluteal region of the patient. . . .
>
> Revitalization follows diencephalon implantation. The children are more alert, fresh, and balanced; they have better appetites and a more restful sleep. They take a more active part in the daily life of the family and show more interest in their schoolwork. Their intelligence, memory, and capacity for giving attention are advanced by some 6 to 12 months.

Beyond the latest item of Niehans' publicity in *Coronet* for December, 1959, written by Herbert S. Benjamin, M.D., there was an item in a gossip column in the Chicago *American* for Nov. 24, 1959, as follows:

> Gilles Lambert, author of "The Conquest of Age," is being kept under wraps by his publishers because so many people are trying to get to him. His book is the story of the fantastic rejuvenating methods used by Swiss Dr. Niehans, and Lambert is swamped with letters, phone calls and telegrams from would-be patients. Usually the doctor accepts only celebrities. Treatments are $500 each.

MEDICAL NEWS

CALIFORNIA

Harvard Alumni Meeting.—There will be a meeting of the Harvard Medical Alumni Association of Southern California at the California Club, 538 S. Flower St., Los Angeles, at 6:30 p. m., Friday, March 11. Dr. Rolf Lium, Portsmouth, N. H., president of Harvard Medical Alumni Association will be guest speaker. Harvard Medical Alumni wishing to attend this meeting should secure information from Dr. Lowell F. Bushnell, 1321 Vermont Ave., Los Angeles 27.

Personal.—Dr. Edward P. Luongo, Los Angeles, was appointed regional medical director for the West Coast of the Mobil Oil Company. Dr. Luongo had been medical director of General Petroleum Corporation since 1947. General Petroleum became a part of Mobil Oil Company on Jan. 1. Dr. Luongo is a diplomate and founder of the American Board of Occupational Medicine.——Dr. Anthony A. Mira, Forest Hills, N. Y., was appointed medical director of the General Telephone Company of California in Santa Monica. Dr. Mira had been medical director of the New York City Department of Welfare from 1945 to 1954. Since 1957 he has been director of the Bureau of Industrial Health and Workmen's Compensation of the Medical Society of the State of New York.

Health Team Begins African Program.—Mr. Karl Fischer, sanitarian and health educator at the College of Medical Evangelists, flew to Dar es Salaam, capital and principal port city of Tanganyika, East Africa, Jan. 18 to launch a new research and preventive medicine program. He will travel by train and bus some 800 miles inland to his destination near the northern end of Lake Tanganyika. Mr. Fischer will be the first of a team of health and medical specialists who will later locate at Heri Hospital, field headquarters for the program. The Research and Assistance Program, as the project is called, dates back to 1956 when six CME scientists made a comprehensive medical survey of East Africa. This survey was continued during the summer of 1957. In the latter part of 1957 the scientists recommended that CME undertake a four-year research and preventive medicine program. Dr. Harold N. Mozar, Loma Linda, director of the CME School of Tropical and Preventive Medicine, which is heading the program, explained that the purpose of the program "is to give medical assistance with emphasis on health education and preventive medicine. A continuous research effort will be aimed at gathering information about local tropical diseases and their causes." Mr. Fischer will direct construction of living quarters and a health education center and research building for other members of the project when they arrive later. After this initial construction is finished, the first group of 12 Africans will arrive and the first three subjects—housing, sanitation, and agriculture—will begin. Members of this first group are teachers from East Africa. They with their families will come to Heri and live for a period of 18 months. Heri Hospital is 40 miles south of Kogoma, a town at the northern tip of Lake Tanganyika.

CONNECTICUT

Yale Celebrates Sesquicentennial.—The Yale School of Medicine, New Haven, will celebrate a century and a half of existence on Oct. 28-29 of this year. The occasion will be marked by meetings, exhibitions, and addresses. Among the guest speakers will be Sir Howard Florey, of Oxford, England. It was in October, 1810, that the Connecticut General Assembly granted a charter to Yale College for the establishment of the Medical Institution of Yale College and the first medical school in the United States came into being. The first medical faculty at Yale included Eli Ives and Jonathan Knight, who became presidents of the American Medical Association. From the start the Connecticut Medical Society was a partner in the enterprise and worked in close cooperation during the first half century of the school's existence. Other events associated with the sesquicentennial celebration will take place during the academic year 1960-1961. These include an exhibition of medical art at the Yale Art Museum and a scientific meeting to be held in conjunction with the dedication of a new medical school auditorium.

ILLINOIS

Hospital News.—The medical staff at Little Company of Mary Hospital, Evergreen Park, elected the following officers for the 1960 year: Dr. James W. West, president; Dr. Stanley E. Ruzich, president-elect; and Dr. John J. Brosnan, vice-president. Other officers of the staff include Dr. James B. O'Neill, secretary, and Dr. Raymond P. Murphy, permanent treasurer, of Chicago.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

Chicago

Annual Lecture.—The 1960 annual D. J. Davis Memorial Lecture on Medical History will be given at 1 p. m., Wednesday, March 3, in Room 221 of the Dental-Medical-Pharmacy Building of the University of Illinois, 1853 W. Polk St. The lecturer will be Barry J. Anson, Ph.D., chairman and Robert Laughlin Rea Professor of the department of anatomy, Northwestern University Medical School. His subject will be "Mediaevel Medicine: Pre-Christian Fabric and Present-Day Remnants."

Annual Clinical Conference.—The Chicago Medical Society will hold its 1960 annual clinical conference at the Palmer House March 1-4. The program lists the following out-of-state participants:

Drs. Michael E. DeBakey, Houston, Texas; John Beach Hazard and Eugene F. Poutasse, Cleveland; John I. Nurnberger, Indianapolis; Howard P. House and Morton D. Leigh, Los Angeles; Thomas E. Machella, Philadelphia; Raymond J. Jackman, Oscar T. Clagett, William G. Sauer, and Louis A. Brunsting, Rochester, Minn.; Robert J. Coffey, Washington, D. C.; Edward H. Kass, Leo P. Krall, and Edward A. Gaensler, Boston; Sol Sherry and Willard M. Allen, St. Louis; Thomas H. Holmes III and Clement A. Finch, Seattle; William H. Zinkham, Baltimore; Horace H. Zinneman, Minneapolis; Rulon W. Rawson, New York City; H. William Clatworthy Jr., Columbus, Ohio; and Richard H. Egdahl, Richmond, Va.

Panel discussions are planned on control of the spread of cancer and reactions to drugs. A clinical pathological conference will be held the afternoon of March 1. Film lectures will be held each morning and television programs will be presented each afternoon. Instructional courses and scientific exhibits are planned. A ladies' program is arranged. Registration fee for nonmembers is $10. For information, write the Chicago Medical Society, 86 E. Randolph St., Chicago 1.

Meeting on Medical History.—There will be a meeting of the Society of Medical History of Chicago at the Institute of Medicine (Fourth Floor, 86 E. Randolph St.) on Wednesday, Feb. 17, 8 p. m. This is an open meeting; all are welcome. The program will be as follows:

Dr. Morris Fishbein, editor, *Excerpta Medica*, "Evolution of Quackery."

Dr. Frederick Stenn, assistant professor of medicine, Northwestern University Medical School, "The Historic Importance of the McCormick Institute for Infectious Diseases."

For information, write Dr. Leo M. Zimmerman, 55 E. Washington St., Chicago 2, secretary.

Hospital Builds Research Building.—Presbyterian-St. Luke's Hospital has received a one-million-dollar gift from John F. Jelke Jr., retired Chicago manufacturer. The gift will be used by the hospital toward the construction of its new medical science research building which presently is under construction. The building, named the Jelke Memorial Building, eventually will consist of 15 floors. The lower floors will be devoted to laboratories, operating suites, observation galleries, and seminar class rooms, and upper floors devoted to bed-patient areas. The gift will enable the hospital to proceed with the completion of the presently planned portion of the ultimate building.

INDIANA

Society News.—At its annual business meeting on Dec. 13, the Indiana Association of Pathologists elected the following officers: Dr. John D. Stepleton, Richmond, president-elect; Dr. Anthony Pizzo, Bloomington, board member; Dr. Leon L. Blum, Terre Haute, installed as president; Dr. Lester H. Hoyt, Indianapolis, reelected councilor; and Dr. David L. Adler, Columbus, assemblyman.——The officers of the Indiana Roentgen Society, Inc., are: president, Dr. John R. Lionberger, South Bend; president-elect, Dr. Chester A. Stayton Jr., Indianapolis; and secretary-treasurer, Dr. David E. Wheeler, 1500 N. Ritter, Indianapolis, Ind. Meetings are held twice a year; the first Sunday in May and during the fall meeting of the Indiana State Medical Association.

Personal.—The Evansville Board of Health on Dec. 16 appointed Dr. Arnold W. Brockmole as director of the City-County Health Department to succeed Dr. Minor Miller, who died in November. Dr. Brockmole, former assistant to Dr. Miller, left Evansville early last year to head the health department in Butte County, Calif.——Dr. Dorothy L. Carter, a native of England, has joined Miles Products, Division of Miles Laboratories, Inc., Elkhart, as research and medical director. Dr. Carter's responsibilities include the administration of all research and medical activities pertaining to the Miles Products division and the coordination of the division's research and medical policy with that of the parent company.

KENTUCKY

Dr. Glass Honored.—On Dec. 13 citizens of Henderson honored Dr. James G. Glass, Henderson, "for 50 years of dedicated medical service to mankind." The physician was honored in a special ceremony at the First Baptist Church. Meharry Medical College, his alma mater, recently presented Dr. Glass with the "President's Award" for 50 years of service —1908-1958.

MASSACHUSETTS

Fund for Research in Ophthalmology.—Establishment of the Max, Martha and Alfred M. Stern Fund at Harvard University, Boston, for research in ophthalmology "and for studies regarding glaucoma and cataract . . . or closely related to the diseases of the eye" was announced by Dr. George P. Berry, dean of the faculty of medicine. The gift of $125,000 was made to the university under the terms of a living trust created by the late Mrs. Martha Stern, of Cincinnati, widow of Mr. Max Stern and mother of the later Alfred M. Stern, Harvard alumnus. Under the terms of the gift extension of the studies into broader fields of ophthalmology may be made in the future "if it is thought that such extension would fruitfully add to knowledge about the eye and its diseases." The studies are carried on in the Howe Laboratory of Ophthalmology of the Harvard Medical School and the Massachusetts Eye and Ear Infirmary.

University News.—An International House for single and married foreign and American students and their families will be developed by the Harvard School of Public Health on Park Drive in Boston's Fenway area following the purchase of three apartment buildings. A committee sponsoring an effort to raise funds to finance renovations of the three buildings is organized. Present plans include provision for 70 living units, common rooms, library, and a recreation area as well as redecorating and furnishing throughout.——Manfred L. Karnovsky, Ph.D., associate professor, was named acting head of the department of biological chemistry in the Harvard Medical School, Boston, He fills a vacancy created through the resignation of Eric G. Ball, Ph.D., who served as acting head of the department since December, 1958, and who requested to be relieved of his duties because of his responsibilities as chairman of the division of medical sciences and his teaching and research.

MISSOURI

Physicians Meeting in Columbia.—The American College of Physicians will hold its Missouri regional meeting Saturday, Feb. 20, at the auditorium of the University of Missouri School of Medicine, Columbia. Dr. Wesley W. Spink, Minneapolis, vice-president of the college, will speak at the luncheon at the Missouri Student Union Building. The program includes 13 papers plus 11 papers to be read by title. A symposium on active immunization will be opened by Dr. Spink. A social hour and dinner will be held at the Daniel Boone Hotel beginning 6:30 p. m. Dr. Paul O. Hagemann, St. Louis, is governor of the college for Missouri. For information, write the American College of Physicians, 4200 Pine St., Philadelphia 4.

NEW YORK

Seminar on Advances in Rehabilitation.—The American Academy of Physical Medicine and Rehabilitation, the State University of New York Downstate Medical Center, and the Kings County Chapter, American Academy of General Practice will sponsor a seminar, "Recent Advances in Rehabilitation Medicine," Friday and Saturday, April 15 and 16, at the Downstate Medical Center, 450 Clarkson Ave., Brooklyn 3. The seminar is supported by a grant from the American Rehabilitation Foundation. A. A. G. P. registrants are entitled to 12 hours of category I credit. For information, write the Downstate Medical Center at the above address.

Fraternity Lecture.—Allen O. Gamble, Ph.D., manpower evaluation and development officer for the National Aeronautics and Space Administration, gave the Alpha Omega Alpha Lecture at Albany Medical College, Jan. 28. His lecture was entitled "Testing, Selection and Training of Astronauts." Dr. Gamble was named to his present post in November, 1958. NASA is a 10,000-man federal research and development agency charged with the responsibility for the nation's civilian space exploration and aeronautical research. Dr. Gamble is in charge of the agency's examining, selection, college recruiting, training, and graduate education programs.

Society News.—The New York Proctologic Society elected the following 1960 officers: president, Dr. Saul Schapiro, Brooklyn; vice-president, Dr. Maus W. Sterns Jr., New York City; and secretary-treasurer, Dr. Norman L. Freund, Brooklyn.——Dr. William A. Brumfield Jr., White Plains, Westchester County health commissioner was elected president of Annual Health Conference Inc., a nonprofit organization chartered by the Secretary of State which sponsors the Annual Health Conference. Other sponsors are the New York State Health Department, the New York State Public Health Association, the Association of School Physicians and School Nurse-Teachers and New York State Health Officers Association. Other officers elected are Dr. Thomas E. Snyder, East Syracuse, vice-president; Dr. Granville W. Larimere, Albany, secretary; Dr. James J. Quinlivan, Albany, assistant secretary; and Marion L. Henry, Delmar, treasurer. The 56th Annual Health Conference will be held May 23-26 in New York City.

New York City

Dr. Goldberger Honored.—Dr. Isidore H. Goldberger, director of health education emeritus of the Board of Education of the City of New York, and clinical professor of pediatrics at New York University School of Medicine, was the guest of honor at the 13th anniversary dinner tendered by the medical board of the Morrisania City Hospital, of which he was a founder, on Saturday, Dec. 19.

Annual Lecture.—The department of dermatology and syphilology, New York University Post-Graduate Medical School, announced that the third annual Howard Fox Memorial Lecture will be delivered by Dr. Robert A. Nelson Jr. on Tuesday, Feb. 16, 8 p. m., in Classroom B of Alumni Hall, 550 First Ave. Dr. Nelson is senior investigator, Howard Hughes Medical Institute, and research professor of medicine, University of Miami School of Medicine, Gainesville, Fla. The title of his talk will be "Immunologic Mechanisms of Resistance to Microbial Infection and to Transplantation of Homologous Tissues."

New Professorship in Cardiovascular Disease.—A new research professorship in cardiovascular disease was established at the Columbia University College of Physicians and Surgeons. The chair, called the Westchester Heart Association Professorship of Cardiovascular Research, is supported partially by a grant from the Westchester Heart Association, Inc. Dr. Andre F. Cournand, professor of medicine at Columbia and a joint winner of the 1956 Nobel Prize in Medicine, has been named first incumbent of the new professorship. Dr. Cournand has been at Columbia since 1930 and has been director of the Cardio-Pulmonary Laboratory Division for 15 years. The Westchester Heart Association, a chapter of the American Heart Association, was founded in 1950 by a group of Westchester County doctors. The chapter operates the Cardio-Respiratory Laboratory at Grasslands Hospital in Valhalla, N. Y.

Personal.—Dr. Griffith J. Winthrop was appointed assistant medical director at E. R. Squibb & Sons. Dr. Winthrop until recently was in private practice in Canandaigua, N. Y.——Dr. Theodore G. Klumpp, president of Winthrop Loboratories, was elected to the board of directors of Sterling Drug Inc. Winthrop Laboratories is Sterling's major pharmaceutical division. Dr. Klumpp had been chief of the Drug Division, U. S. Food and Drug Administration, and director of drugs, food and physical therapy and secretary of the council on pharmacy and chemistry, American Medical Association.——Dr. Harry Lane Robinson, assistant clinical professor at New York University's College of Dentistry for the past two years, was named professor and chairman of the department of pathology. Dr. Robinson is an attending pathologist at the Veterans Administration Hospital, and an attending surgeon at Mother Cabrini Hospital, Manhattan.

OHIO

Annual Lectures in Cincinnati.—On Saturday and Sunday, April 9 and 10, Dr. John W. Hope, director, department of radiology, Children's Hospital of Philadelphia, will deliver the 12th annual Joseph and Samuel Freedman Lectures in Diagnostic Radiology at the University of Cincinnati College of Medicine. There will be no charge for the lectures. Radiologists desiring to attend are requested to write Dr. Benjamin Felson, X-Ray Department, Cincinnati General Hospital.

VIRGINIA

Regional Meeting of Physicians.—The American College of Physicians will hold a regional meeting for Virginia Saturday, Feb. 20, at the Medical School Amphitheatre of the University of Virginia, Charlottesville. The following papers include invited authors:

Use of Antibiotics, Dr. Calvin M. Kunin, Boston.
The Pathogenesis of Glomerulonephritis, Drs. Alvin E. Parrish, Norman C. Kramer, Fred E. Hatch, Mary F. Watt, John S. Howe, Washington, D. C.
The Role of Alveolar Machrophage in Resistance to Tuberculosis, Quentin N. Myrvik, Ph.D.
Cerebral Vascular Disease, Dr. Fritz E. Dreifuss, Charlottesville.
A Re-evaluation of the Hemodynamic Changes in Cirrhosis of the Liver, Dr. W. Dean Warren, Charlottesville.
Pathophysiology of Hyperbilirubinemic States, Dr. Aubrey Brown, Charlottesville.

Dr. Chester K. Jones, Boston, regent of the college, will present an address at the evening dinner session. Governor of the college for Virginia is Dr. Kinloch Nelson, Richmond. For information, write the American College of Physicians, 4200 Pine St., Philadelphia 4.

WEST VIRGINIA

Ease Requirements for Foreign Physicians.—The West Virginia Medical Licensing Board has liberalized the requirements for service by foreign educated physicians in state institutions. This action was taken at the winter meeting of the board held in Charleston on Jan. 11. Governor Cecil H. Underwood proposed that legislation be enacted governing the employment of foreign trained physicians in the state institutions. The effect of the board's decision will permit foreign trained physicians to practice in state hospitals and institutions for a period of one year with the understanding that permits issued may be renewed indefinitely. Temporary authorizations for foreign graduates entering West Virginia for internships or residencies will be granted providing such graduates fulfill all the requirements of the board as stipulated in the regulations, and provided that they agree to appear in person at the next meeting of the Medical Licensing Board. The revised regulations require all foreign graduates to submit their medical credentials to the board for evaluation by the proper agencies. Such graduates serving in state institutions will be required to take the regular licensing examination as soon as they become eligible. Before the regulations were revised, graduates of foreign medical schools were permitted to work, under supervision, as residents and interns in hospitals not more than four years.

GENERAL

Psychoanalytic Association Changes Address.—The American Psychoanalytic Association announced the change of address of its central office, effective Dec. 15 to One East 57th St., New York 22 (fifteenth floor); Telephone: PLaza 2-0450.

Surgical Meeting in Hawaii.—The eighth congress of the Pan-Pacific Surgical Association will be held Sept. 27-Oct. 5 in Honolulu, Hawaii. All members of the medical profession are eligible to register. Ten surgical specialty sections will be held simultaneously. Information and brochures may be obtained by writing Dr. Forrest J. Pinkerton, Director General, Suite 230, Alexander Young Building, Honolulu 13, Hawaii.

Three Researchers Receive Award.—The first-place 1959 Glycerine Research Award of the Association of American Soap and Glycerine Producers, Inc., was awarded to Dr. Stanley W. Jacob, assistant professor of surgery, University of Oregon Medical School, Portland; Dr. Ernest M. Barsamian, of Harvard Medical School, Boston; and Samuel C. Collins, Ph.D., of the Massachusetts Institute of Technology. The prize-winning research project involved the successful transplantation of puppy hearts, which had been dehydrated and supercooled, using glycerine as an "anti-freeze." The work was done under the auspices of Harvard and MIT.

Congress on Gerontology in San Francisco.—The International Association of Gerontology will meet in San Francisco, for its fifth International Congress of Gerontology, Aug. 7-12. The program of the congress is planned in four sections: the biological sciences; clinical medicine; psychology and the social sciences; and social welfare. Each section will hold scientific sessions for the presentation of papers, and four scientific sessions will meet simultaneously. There will be two plenary sessions and at least one open, public meeting. English will be the official language for the congress. The registration fee will be $25 for all who register before May 31; thereafter the registration fee will be $30. Those desiring to register in advance should so inform the president of the congress, Mr. Louis Kuplan, P. O. Box 2103, Sacramento 10, Calif.

Award for Paper on Biological Psychiatry.—The Society of Biological Psychiatry is offering an annual award made possible by the A. E. Bennett Neuropsychiatric Research Foundation. The A. E. Bennett Award of $500, part of which is to be used for traveling expenses to the society's meeting, will preferably be given to a young investigator not necessarily a member of the Society of Biological Psychiatry, for work which has recently been accomplished and not published. The paper will be read as part of the program of the annual meeting and will be published with the other papers read at that meeting in the book, "Biological Psychiatry," volume III. The honorarium will be awarded at the annual banquet. Submit papers in quadruplicate to Dr. Harold E. Himwich, Chairman, Committee of Award, Galesburg State Research Hospital, Galesburg, Ill. Deadline for manuscripts is April 30.

Meeting of Methodist Hospitals Group.—The annual convention of the National Association of Methodist Hospitals and Homes will be held Feb. 16-18 at the Deshler-Hilton Hotel, Columbus, Ohio, with Mr. Victor B. Hann, president of the association, Mechanicsburg, Pa., presiding at the opening general assembly. Secretary of Health, Education, and Welfare Arthur S. Flemming will give the keynote address at the first general assembly, Feb. 17. Group meetings will be held Feb. 17-18 and among the themes to be considered are the following: employee-employer relations, sharing today's administrative problems, and standards for nursing care. A discussion on preparation and recommendations for the White House Conference on Aging is planned and a panel discussion on Feb. 17 will consider "Our Common Objectives and How We Attain Them." A banquet will be held the evening of Feb. 17. For information, write the Board of Hospitals and Homes of the Methodist Church, 740 Rush St., Chicago 11.

Scholarships in Allergy for Students.—The Scientific and Educational Council of the Allergy Foundation of America announced the availability of a limited number of quarterly or summer scholarships at $600 each in approved medical schools in the United States and Canada. These scholarships are available to students who have "creditably completed" their second or third year in medical school and are to be for a minimum of eight weeks during which the student will receive training and experience both in clinical and research allergy. Each medical school has been invited to submit the name of one applicant through the dean's office with a letter from the dean in support of the candidate's application, outlining the candidate's medical school record, the proposed research project, and under whose sponsorship it will be carried out. Direct applications from students will not be considered. All applications must be filed no later than March 1 and should be sent to Dr. Robert A. Cooke, Chairman, Scientific & Educational Council, Allergy Foundation of America, 801 Second Ave., New York 17. This program of student summer scholarships was initiated by the foundation in 1956, when 10 such scholarships were awarded. Twenty scholarships were awarded in 1957, 22 in 1958, and 25 in 1959.

Council for Baby Care Formed.—Ernest G. Osborne, Ph.D., professor of education and associate in the Guidance Laboratory, Teachers College, Columbia University, New York City, is chairman of the board of the new organization known as the National Baby Care Council. The board of directors includes persons in medicine, public health, education, nursing, social service, hospitals, research, community organization, and communications. "The purpose of the National Baby Care Council is to concentrate attention on the baby from birth to the age of about two years," Dr. Osborne said. The council will attempt the following:

Bring into one body of knowledge all that is known about baby health, education, and welfare;
Identify areas in which more knowledge is needed and sponsor or recommend research to fill the gaps;
Serve as a channel of communication between those (professions) concerned with baby care;
Make information on baby care available, in understandable terms, to mother, family, professions, and community.

Financial support for the National Baby Care Council comes from the nation's diaper service industry. The council will conduct its program through an organization of professional committees. Each committee will be under the direction of a member of the board of directors selected from the professional field in which the committee functions. Two immediate projects to be sponsored by the council are the publication of a mother's handbook on the prevention of diaper rash and a training course for teenage girls in baby sitting. The address of the council is 1620 Locust St., Philadelphia 3.

Society News.—The **American Board for Certification in Orthotics and Prosthetics, Inc.,** held its annual meeting at Dallas, Texas, Oct. 20. Dr. Roy M. Hoover, Roanoke, Va., was the retiring president of the board. The new officers are: president, Howard Thranhardt, C. P., Atlanta, Ga.; vice-president, Dr. Eugene E. Record, Boston; secretary-treasurer, M. P. Cestaro, Washington, D. C. Dr. George T. Aitken, of Grand Rapids, Mich., was elected to the board by nomination of the American Academy of Orthopaedic Surgeons. Alvin Muilenburg, C. P., of Houston, Texas, was elected to the board by nomination of the American Orthotics and Prosthetics Association. Mr. Glenn E. Jackson is executive director of the board, with headquarters at 919 18th St., N.W., Washington, D. C.——**Phi Lambda Kappa,** medical professional fraternity, announced the election of the 1960 executive officers. Dr. Edward L. Axelman, Darby, Pa., is the new fraternity president; president-elect is Dr. Benjamin F. Bornstein, Boston. Reelected secretary is Dr. Abram H. Persky, 1205 Spruce St., Philadelphia, and reelected treasurer is Dr. Lawrence J. Thomas, Washington, D. C.——Herold R. Cox, Sc.D., was elected president of the **Society of American Bacteriologists.** Dr. Cox, director of virus research at Lederle Laboratories Division, American Cyanamid Company, is the first representative of industry ever elected to the post. His term will begin July, 1960. The new vice-president is Dr. John E. Blair, New York City. E. M. Foster, Ph.D., Madison, Wis., and John H. Bailey, Ph.D., of the Sterling-Winthrop Research Institute, will continue as secretary and treasurer, respectively.

Meeting on Pediatrics in Atlantic City.—The spring session of the American Academy of Pediatrics will be held April 20-22 at the Chalfonte-Haddon Hall, Atlantic City, under the presidency of Dr. William W. Belford, San Diego, Calif. Seven panel sessions are planned with the following titles and moderators:

What Kills Newborn Infants, Dr. Stuart S. Stevenson, Jersey City.
The Time to Operate on a Patient with Congenital Heart Disease, Dr. Daniel F. Downing, Philadelphia.
Present Status of Poliomyelitis Immunization, Dr. Joseph Stokes Jr., Philadelphia.
Drug Therapy in Pediatrics, Dr. Hans G. Keitel, Philadelphia.
Eastern Equine Encephalomyelitis, Dr. Roscoe P. Kandle, Trenton, N. J.
Neoplasms in Infants and Children, Dr. James B. Arey, Philadelphia.
Can the New Pediatrics be Practiced, Dr. Carl C. Fischer, Philadelphia.

A symposium, "What the 1960 White House Conference on Children and Youth Means to Pediatrics," is planned for the morning of April 22. Television presentations to be shown concurrently with the general sessions daily will include pediatric dermatology, pediatric orthopedics, pediatric radiology, practical ophthalmology for pediatricians, pediatric asthma, and pediatric endocrinology. Technical and scientific exhibits are planned. A program of entertainment will include the banquet at 8 p. m., April 21. Registration fee for members is $6 and for nonmembers out of school more than five years, $25. For information, write the executive office of the academy, 1801 Hinman Ave., Evanston, Ill.

Research Fellowship Program.—The Southeast Asia Treaty Organization through the Conference Board of the Associated Research Council Committee on International Exchange of Persons, announced its research fellowship program for 1960-1961. The aim of the SEATO Program is to encourage the study and research (preferably leading to publication) of such social, economic, political, cultural, scientific, and educational problems as "give insight into the present needs and future development of Southeast Asia and the Southwest Pacific, viewed against a background of SEATO objectives." A limited number of advanced research fellowships is offered for 1960-1961 to candidates from member states (Australia, France, New Zealand, Pakistan, the Philippines, Thailand, the United Kingdom, and the United States). A candidate must be a national of a member state and should plan to undertake his research in SEATO countries situated within the treaty area (the general area of Southeast Asia, including also the entire territories of the Asian Parties, and the general area of the Southwest Pacific, not including the Pacific area north of 21°30′ north latitude). Study in other countries may be authorized only under exceptional circumstances. The applicant's project should be of interest to SEATO and, preferably, to two or more SEATO member countries, rather than to a single one, but should not involve an extravagant travel plan. Grants are intended for well-established scholars. Candidates will be selected on the basis of their special aptitude and experience for carrying through a major project of research. Academic qualifications (the doctoral degree or its equivalent), professional experience beyond the completion of training, and published material will be taken into account. Preliminary screening of American candidates will be by the Committee on International Exchange of Persons of the Conference Board of Associated Research Councils, which will recommend candidates to the Department of State and the President's Board of Foreign Scholarships. It is expected that only one or two grants will be available to candidates from the U. S. The grant will provide a monthly allowance of $400 and tourist-class return air travel to the country or countries of research. Grants may be authorized for periods of from 4 to 10 months. Application forms and information may be obtained from the Conference Board of Associated Research Councils, Committee on International Exchange of Persons, 2101 Constitution Ave., Washington 25, D. C. Applications should be submitted no later than March 1.

EXAMINATIONS AND LICENSURE

MEDICAL SPECIALTY BOARDS

American Board of Anesthesiology: *Written.* Various locations, June 24. Final date for filing application was January 10. *Oral.* Miami Beach, April 25-30. Applications already on file. Sec., Dr. Forrest E. Leffingwell, 217 Farmington Ave., Hartford 5, Conn.

American Board of Internal Medicine: *Oral.* San Francisco, March 30-April 1; New York City, Nov. 14-17. Closing date for filing application is Jan. 2 and July 1. *Written.* Oct. 17. Closing date for filing application is May 1. *Oral. Gastroenterology.* Philadelphia, March 11-12. Final date for filing application was January 15. Sec.-Treas., Dr. William A. Werrell, One West Main St., Madison 3, Wis.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. St. Louis, April 10-12. In order to be eligible a candidate must have his application filed at least six months before the examination time. Sec., Dr. Donald D. Matson, 300 Longwood Ave., Boston, Mass.

American Board of Obstetrics and Gynecology: *Part II, Oral and Clinical.* Chicago, April 11-16. Final date for filing application was August 1. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Written.* Jan. 23, 1961. Deadline for filing applications is July 1. *Oral.* San Francisco, May 9-13; Chicago, Oct. 3-7. Sec., Dr. Merrill J. King, Box 236 Cape Cottage Branch, Portland, Maine.

American Board of Orthopaedic Surgery: *Part I,* Nashville, Denver and Philadelphia, Apr. 13-14. Deadline for receipt of applications was Nov. 30. *Oral and Written, Part II.* Miami Beach, Jan. 3-5, 1961. Final date for filing application is July 1. Sec., Dr. Sam W. Banks, 116 South Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Oral,* Chicago, Oct. 3-6. Final date for filing application is April 1. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: Memphis, April 21-23. Final date for filing application is March 7. *Examination in Forensic Pathology.* Memphis, April 22. Final date for filing application is March 7. Sec., Dr. Edward B. Smith, Indiana University Medical Center, 1100 W. Michigan St., Indianapolis 7.

American Board of Pediatrics: *Written.* New York City, January 1961. Final date for filing application is Dec. 1. Administrative Sec., Mrs. Eleanor J. Mitchell, Rosemont, Pa.

American Board of Physical Medicine and Rehabilitation: *Oral and Written.* New York, June 17-18. Sec., Dr. Earl C. Elkins, Mayo Clinic, Rochester, Minn.

American Board of Plastic Surgery: *Oral and Written.* Milwaukee, May 1960. Final date for filing application was January 1. Corresponding Secretary, Mrs. Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8, Mo.

American Board of Proctology: *Oral and Written, Parts I and III,* Philadelphia, Sept. 24. Final date for filing application is June 30. Sec., Dr. Stuart T. Ross, 520 Franklin Ave., Garden City, N. Y.

American Board of Psychiatry and Neurology: San Francisco, March 14-15; New York, New York, Dec. 12-13. *Child Psychiatry.* Chicago, April 25-26. Sec., Dr. David A. Boyd, Jr., 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology: *Examination.* Cincinnati, June 6-10; Dec. 5-9. Deadline for filing applications for the June examination was Jan. 1. Filing deadline for the December examination is July 1. A special examination in Nuclear Medicine (for those diplomates in Radiology or Therapeutic Radiology) will be offered provided there are sufficient applications. Sec., Dr. H. Dabney Kerr, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Oral Examinations (Part II):* New Orleans, Mar. 14-15; Kansas City, Kans., May 16-17; and Los Angeles, May 19-20. Sec., Dr. John B. Flick, 1617 Pennsylvania Blvd., Philadelphia 3.

Board of Thoracic Surgery: *Oral.* May 1960. Final date for filing application was Dec. 1. Sec., Dr. Wm. M. Tuttle, 1151 Taylor Ave., Detroit 2.

American Board of Urology: *Written.* December. *Oral-Clinical.* Chicago, February 1961. Exec. Sec., Mrs. Ruby L. Griggs, 30 Westwood Road, Minneapolis 26.

GOVERNMENT SERVICES

PUBLIC HEALTH SERVICE

Mental Health Conference.—The conference of the surgeon general of the Public Health Service with state and territorial mental health authorities in January recommended that:

1. The Secretary of Health, Education, and Welfare propose to the Congress legislation to amend existing social security laws so that they do not discriminate against persons with any type of illness, mental or physical, and in the mean time that the present wording of the portion of the Social Security Act governing public assistance benefits be interpreted so as to specify that only persons physically residing in a mental hospital be excluded from assistance benefits.
2. General hospitals, particularly teaching hospitals, be encouraged to admit alcoholics for treatment.
3. The Public Health Service be requested to provide short courses in appropriate places throughout the country to give instruction and orientation in the development of alcoholism program activities.
4. Wherever appropriate, alcoholism services be incorporated with other community activity and that mental health centers, if they are not now serving alcoholics, be encouraged to do so.
5. The Public Health Service provide leadership in working with the states in research on the emotional problems of children.
6. The Public Health Service conduct or support a survey of current patterns of mental health education and information programs of the various states with particular attention to program content, staff, techniques, evaluation methods, and results and publish a report that can be used as a resource manual to be made available especially to state mental health authorities.
7. The Public Health Service encourage the development of comprehensive diagnostic and treatment services for mentally retarded persons, integrated with other medical and related services at the local community level.
8. The Public Health Service investigate through sociological and epidemiologic studies the needs of mentally retarded and border-line adults and the resources available for them.
9. The Department of Health, Education, and Welfare emphasize in its training and assistance programs the subject of mental retardation.
10. Mental retardation be included as a major agendum at the 1961 conference of the surgeon general with state and territorial mental health authorities.
11. State mental health authorities be supplied with copies of the report, "School Mental Health Activities of State Mental Health Authorities," and that each state mental health authority be requested to provide supplementary information about its activities in the school mental health area to be included in a periodic revision of the report.
12. Wherever feasible, the state mental health authorities take the initiative in establishing appropriate liaison mechanisms with departments of education so that they can together, in a mutual relationship and on a joint basis, analyze and develop the comprehensive school mental health programs in the state.
13. The staff for school mental health consultation services of the community services branch be expanded in order to provide more intensive services to the states in which a need for additional services exists.
14. The Public Health Service expand the programs for the training of school mental health personnel.
15. The Public Health Service be encouraged to contract for special studies in school mental health programs.

Hospital to Close.—The Public Health Service Hospital for tuberculosis patients at Manhattan Beach, Brooklyn, will be closed on June 15. Beneficiaries of the service suffering from tuberculosis will receive care at selected Public Health Service hospitals or at a nonservice hospital under a contractual arrangement. Employees will be given all possible assistance in finding employment with other Public Health Service installations and other federal and private agencies. The decision to close the 350-bed hospital, operated by the Public Health Service since 1950, was made because of the decreasing number of patients with tuberculosis. Since 1955 the average number of patients has declined from 339 to 210. Meanwhile, the annual cost of operation rose from $1,334,000 to $1,610,000.

New Appointments.—Dr. Howard P. Rome, professor of psychiatry at the graduate school of medicine, University of Minnesota, Mayo Foundation for Medical Education and Research, Rochester, Minn.; Dr. John T. Cowles, professor of psychology at the school of medicine, University of Pittsburgh; and Dr. Robert B. Howard, dean of the University of Minnesota Medical School, Minneapolis; were each appointed to serve a three-year term on the selection committee for the senior research fellowship program of the National Institutes of Health.

New Publication.—The importance of area-wide planning in the development of a coordinated hospital system is stressed in the Public Health Service publication, "Principles for Planning the Future Hospital System," which is a report of the proceedings of regional conferences held in Chicago, New Orleans, Salt Lake City, and Washington, D. C., in April and May, 1959, under the joint sponsorship of the American Hospital Association and the Public Health Service.

Training in Public Health.—The Public Health Service is accepting applications from professional health workers for graduate training in public health for the 1960-1961 academic year. Congress first established this program in 1956. Over the past four years 158 physicians have been awarded such traineeships. The awards provide stipends for living expenses of the trainees in addition to tuition and fees. Applications should be submitted by March 1.

Venereal Disease on Increase.—The incidence of early infectious syphilis for the fiscal year 1959 was up 22.8% over that of fiscal 1958. If the current trend continues, the number of persons with early infectious syphilis will soar to over 10,000 in the fiscal year 1960. This rise was accompanied by a 7.8% rise in the incidence of gonorrhea for the same period.

Retirement.—Dr. C. J. Van Slyke, deputy director of the National Institutes of Health, retired after 30 years' service. He was appointed the first deputy director of the Institutes in 1958 after having served as associate director since 1952. Dr. Kenneth M. Endicott, presently associate director for training programs, will be given additional responsibilities involving the grants program.

FOOD AND DRUG ADMINISTRATION

Court Actions.—Bulk wheat, flour, and corn grits contaminated by rodents and insects accounted for 214 of the 500 tons of unfit foods removed from the market in November. Spoilage, parasitic cysts, and filth were found in 44 tons of haddock fillets, breaded shrimp, whitefish, trout, and anchovies. Nearly 30 tons of canned tomatoes and catsup containing fly eggs and maggots were seized in 10 actions. Another 30 tons consisted of moldy frozen blueberries, spoiled apricot concentrate, and insect-contaminated maraschino cherries. Spoilage in a 15-ton shipment of frozen chickens caused its removal from the market. Seized as economic cheats were 92,000 tablets of low-strength vitamin products and 19 tons of other foods including canned peas and fruit jams failing to meet requirements of the respective definitions and standards of identity, and canned peppers and raw popcorn with less of the product than was declared on the label.

Eleven of the 19 drugs and devices seized were alleged to be misbranded by false and misleading claims. Three nonprescription products containing a so-called "appetite depressant" were offered to reduce weight. A plastic "breather bag" was offered for $1 as a treatment for foot and leg cramps. Users of the bag were instructed to do the following actions five times: take a deep breath, exhale into the bag through the mouth, and inhale contents of the bag through the nose. A vitamin product in timed-release capsules was offered with claims that it would provide "pep in minutes that lasts for hours." The stimulant in each capsule was found to be caffeine in an amount equal to that provided in 1 to 1.5 cups of coffee. A "prescription dentrifice" sold directly to the public was represented in leaflets as a treatment for bleeding gums, pyorrhea, gingivitis, and other oral conditions.

New Drug Removed from the Market.—A California manufacturer's authorization to market a new drug was revoked and the product taken off the market because the company completely disregarded the specific conditions of production and use that it proposed in obtaining authorization to market the product (Pre-Creatine). This drug was offered for increasing available energy to muscles and nerves damaged by cardiac and neuromuscular diseases. The revocation was based on the fact that (1) manufacturing, packaging, and labeling of the product was performed by a different firm than was named in the application for authorization, (2) other ingredients than those listed were used, (3) the approved control procedures for identification and assay of raw materials and the finished product were not followed, and, (4) an important ingredient was obtained from a different source than was stated. Such complete disregard by the manufacturer of the essential safety precautions included in a new drug application is rare.

Purveyor of Rotten Eggs Jailed.—Harry Cohen, convicted principal in the East Coast diversion of rotten incubator reject eggs into foods, pleaded guilty to charges of violating terms of a five-year probation and was sentenced to three months in jail. Inspectors proved that Cohen was back in business between Jan. 16 and March 5 and was responsible for buying incubator reject eggs from Connecticut hatcheries and shipping them to New York. There these rotten eggs would have been broken and packed for sale in 30-pound cans as frozen whole eggs. The court ordered that Cohen's probation be continued when his jail sentence expires.

Voluntary Corrective Actions.—Two Washington state bakers took the lead in voluntary plant improvements with programs costing $64,400. A total of $174,965 went into 19 individual plant improvements to assure production of clean, wholesome products, according to food manufacturers and warehousemen. An additional 82 actions by food firms to protect the public resulted in the destruction or diversion to nonfood use of 246 tons of unfit foods. Drug firms voluntarily destroyed old and substandard drugs valued at $2,968.

DEATHS

Baert, George Henry Ⓜ Grand Rapids, Mich.; University of Pennsylvania Department of Medicine, Philadelphia, 1893; served on the board of education; died Nov. 5, aged 89.

Ballard, Marshall Paul Ⓜ Delphos, Kan.; University of Kansas School of Medicine, Kansas City, Kan., 1936; interned at St. Mary's Hospital in Kansas City, Mo.; served as health officer of Ottawa County; on the staff of the St. Joseph's Hospital in Concordia; died Nov. 20, aged 50.

Barnett, William Edwin Ⓜ Dallas, Texas; Indiana University School of Medicine, Indianapolis, 1931; interned at the Indiana University Hospitals, Indianapolis, where he served a residency; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; served on the faculty of the University of Texas Southwestern Medical School; veteran of World War II and held the American Defense and Pacific Theatre medals; associated with the Baylor University Hospital and the Parkland Memorial Hospital; on the staff of St. Paul's Hospital, where he died Nov. 2, aged 54.

Bartholomew, Don Clio Ⓜ San Diego, Calif.; Detroit College of Medicine and Surgery, 1916; retired from the U. S. Army June 30, 1935; died in the U. S. Naval Hospital Oct. 4, aged 71.

Baumgartner, Conrad, St. Louis; Barnes Medical College, St. Louis, 1895; died in the Alexian Brothers Hospital Nov. 19, aged 85.

Beckford, Samuel McDonald, Henderson, N. C.; Boston University School of Medicine, 1917; died in the Jubilee Hospital Sept. 4, aged 74.

Beecher, Clarence H. Ⓜ Burlington, Vt.; born in Granville, N. Y., Oct. 9, 1877; University of Vermont College of Medicine, Burlington, 1900; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians, of which he was at one time governor; for many years on the faculty of his alma mater, where he served as dean from 1941 to 1945; past-president and secretary of the Vermont State Medical Society, of which he was an honorary member and recipient of the society's distinguished service award; past-president of the Vermont Heart Association; served as mayor of Burlington; consulting physician at the Fanny Allen Hospital in Winooski, Bishop De Goesbriand Hospital, and the Mary Fletcher Hospital; in 1958 the honorary degree of doctor of science was conferred upon him by his alma mater; died in the Mary Fletcher Hospital Nov. 21, aged 82.

Berczeller, Arpod Ⓜ Staten Island, N. Y.; Medizinische Fakultät der Universität, Vienna, Austria, 1929; interned at the Sea View Hospital, where he was associated with the department of bacteriology; died in the Madison Avenue Hospital, New York City, Nov. 28, aged 55.

Bergstein, Joseph Ⓜ Brooklyn; University and Bellevue Hospital Medical College, New York City, 1929; member of the American Academy of General Practice; died Oct. 10, aged 55.

Birchard, Fred Sherman Ⓜ Montrose, Pa.; Medico-Chirurgical College of Philadelphia, 1903; past-president of the Susquehanna County Medical Society; affiliated with the Robert Packer Hospital in Sayre; died Nov. 12, aged 79.

Boccelato, Salvador L. Ⓜ San Antonio, Texas; Memphis (Tenn.) Hospital Medical College, 1913; veteran of World War I; on the staff of Santa Rosa Hospital, where he died Nov. 6, aged 70.

Bohn, Julius Charles Ⓜ Tacoma, Wash.; Washington University School of Medicine, St. Louis, 1901; veteran of World War I; once named "outstanding general practitioner of the year" by the Pierce County Medical Society; died in the Tacoma General Hospital Oct. 31, aged 83.

Bray, Emmett Perleyman, Richmond, Va.; Medical College of Virginia, Richmond, 1922; died Nov. 7, aged 71.

Brecker, Francis Wellington Ⓜ Hartford, Conn.; Tufts College Medical School, Boston, 1928; member of the American Academy of Dermatology and Syphilology; at one time health officer for the town of East Hartford; on the staffs of the Institute of Living, J. J. McCook Memorial Hospital, and St. Francis Hospital, where he died Nov. 3, aged 58.

Brewster, Guy Otis, Florida City, Fla.; Jefferson Medical College of Philadelphia, 1896; died Oct. 28, aged 90.

Britt, Patrick Francis, Syracuse, N. Y.; Syracuse University College of Medicine, 1922; veteran of World War I; for many years associated with St. Mary's Hospital; courtesy member of the staff of St. Joseph's Hospital; died Nov. 14, aged 66.

Ⓜ Indicates Member of the American Medical Association.

Browe, Evelyn Lilian, Brainerd, Minn.; University of Minnesota Medical School, Minneapolis, 1928; member of the American Society of Anesthesiologists; died in St. Joseph's Hospital Aug. 25, aged 57.

Brown, William Marion Ⓜ Livingston, Tenn.; Lincoln Memorial University Medical Department, Knoxville, 1918; died Nov. 5, aged 79.

Cary, Edward Austin Ⓜ Ann Arbor, Mich.; Tulane University School of Medicine, New Orleans, 1947; interned at the University Hospital, where he served a residency; specialist certified by the American Board of Psychiatry and Neurology; on the faculty of the University of Michigan Medical School; veteran of World War II; an officer in the U. S. Naval Reserve from 1950 to 1952; on the staff of the Veterans Administration Hospital; died Nov. 24, aged 35.

Clay, Frank Homer, Longwood, Fla.; Minneapolis College of Physicians and Surgeons, 1910; died Nov. 6, aged 75.

Conwell, John Berchman, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1935; served on the staffs of the Wills Eye Hospital and the Hahnemann Hospital; died Nov. 28, aged 51.

Costolow, William Evert Ⓜ Los Angeles; born in Kirksville, Mo., June 13, 1892; University of Pennsylvania School of Medicine, Philadelphia, 1916; on the faculty of the University of Southern California School of Medicine; specialist certified by the American Board of Radiology; member of the Radiological Society of North America, Inc., of which he was past-vice-president, American College of Radiology, and the American Radium Society, of which he was past-president and secretary; fellow of the American College of Physicians; past-president of the Los Angeles County Medical Association and past-vice-president of the Los Angeles Branch of the American Cancer Society; consultant, Los Angeles Tumor Institute; served as president of the Albert Soiland Cancer Foundation; past-chairman, tumor board, Los Angeles County General Hospital; associated with the California, St. Vincent's, and Santa Fe Coast Lines hospitals; at one time a fellow at the Mayo Clinic in Rochester, Minn.; veteran of World Wars I and II; died in the Good Samaritan Hospital Nov. 22, aged 66.

Couey, Elmer J. Ⓜ Santa Ana, Calif.; College of Physicians and Surgeons of San Francisco, 1900; past-president of the Fresno County Medical Society; for many years practiced in Fresno, where he was associated with the Fresno County Health Department; served as assistant county health officer in Fresno County; died Oct. 25, aged 82.

Cubbins, William Robert Ⓜ Dundee, Ill.; Northwestern University Medical School, Chicago, 1900; member of the founders group of the American Board of Surgery; member of the Western Surgical Association; fellow and a founder of the American College of Surgeons; served on the faculty of Loyola University School of Medicine in Chicago, where he was on the staffs of St. Luke's and Cook County hospitals; died in the Sherman Hospital, Elgin, Nov. 15, aged 85.

Culbreath, Louis W., Stanton, Tenn.; Memphis (Tenn.) Hospital Medical College, 1899; died in Jackson Oct. 4, aged 90.

Curran, Harold Joseph Ⓜ Waterbury, Conn.; Tufts College Medical School, Boston, 1924; fellow of the American College of Surgeons; member of the Industrial Medical Association; died in the Waterbury Hospital Nov. 4, aged 59.

Donahue, John Leo Ⓜ Tucson, Ariz.; Jefferson Medical College of Philadelphia, 1910; specialist certified by the American Board of Psychiatry and Neurology; veteran of World War I; served on the staffs of the Veterans Administration hospitals in Fort Bayard, N. M., and in Tucson; died Nov. 17, aged 73.

Ellis, Henry Avner Ⓜ Kiowa, Okla.; College of Physicians and Surgeons, Dallas, Texas, 1905; died in McAlester Nov. 13, aged 83.

Fasoldt, Laurence Otto Ⓜ Glendale, Ohio; University of Vermont College of Medicine, Burlington, 1937; interned at the St. John's Riverside Hospital in Yonkers, N. Y.; veteran of World War II; member of the Aero Medical Association; associated with the Fort Hamilton and Mercy hospitals in Fort Hamilton and the Maple Knoll Hospital, where he was secretary of the medical staff; died Nov. 22, aged 52.

Fullerton, Lynne Araunah Ⓜ Tacoma, Wash.; University of Minnesota Medical School, Minneapolis, 1916; specialist certified by the American Board of Preventive Medicine; in 1935 appointed medical inspector in the Indian Medical Service with headquarters in Spokane; for many years associated with the U. S. Public Health Service, retiring Sept. 1, 1950; veteran of World Wars I and II; died in the Madigan Army Hospital Sept. 11, aged 68.

Gibbons, Joel Marion Ⓜ Van Nuys, Calif.; born in Sweetwater, Texas, Aug. 12, 1911; College of Medical Evangelists, Loma Linda and Los Angeles, 1936; interned at the Los Angeles County Hospital in Los Angeles; on the faculty of his alma mater; certified by the National Board of Medical Examiners; specialist certified by the American Board of O[illegible] [illegible]mber of the American Academy [illegible] and Otolaryngology and the Aero Medical Association; fellow of the

International College of Surgeons; veteran of World War II; associated with St. Joseph's Hospital in Burbank, White Memorial Hospital in Los Angeles, and the Valley Hospital; died Nov. 16, aged 48.

Hallenbeck, Clive Ewer, Dunkirk, N. Y.; University of Michigan Medical School, Ann Arbor, 1907; on the staff of the Brooks Memorial Hospital; died Nov. 15, aged 77.

Harvey, John Ⓜ Lexington, Ky.; University of Pennsylvania School of Medicine, Philadelphia, 1920; certified by the National Board of Medical Examiners; specialist certified by the American Board of Internal Medicine; member of the American Rheumatism Association and the Central Society for Clinical Research; fellow of the American College of Physicians; veteran of World War II; chairman of the Lexington-Fayette County Board of Health; on the staffs of the Good Samaritan Hospital and St. Joseph's Hospital, where he died Nov. 14, aged 66.

Heath, George Dawson Jr. Ⓜ Madison, Va.; University of Louisville (Ky.) Medical Department, 1907; veteran of World War I; formerly health director of Bloomington, Ill.; died in Staunton Nov. 12, aged 75.

Henderson, James Alfred Ⓜ New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1903; veteran of World War I; served as secretary-treasurer and chief sanitation officer of the New Orleans Board of Health; formerly secretary of the state board of medical examiners; for many years on the staff of the Charity Hospital; died in the Mercy Hospital Nov. 21, aged 78.

Hoover, Lawrence Hites, Clarksville, Va.; Medical College of Virginia, Richmond, 1920; died in South Boston Nov. 20, aged 65.

Hudson, Victor Talmadge Ⓜ Mobile, Ala.; University of Tennessee College of Medicine, Memphis, 1937; interned at the Kansas City General Hospital in Kansas City, Mo.; served a residency at St. Luke's Hospital in Bethlehem, Pa.; member of the Southeastern Surgical Congress; fellow of the American College of Surgeons; veteran of World War II; associated with the Mobile Infirmary, Providence Hospital, and the Mobile General Hospital; died Nov. 12, aged 47.

Hussey, Carlyle Perry Ⓜ Suffern, N. Y.; University of Pennsylvania Department of Medicine, Philadelphia, 1904; associated with the Tuxedo Memorial Hospital in Tuxedo Park and the Good Samaritan Hospital; consulting diagnostician with the Columbia-Presbyterian Medical Center in New York City; died Nov. 1, aged 80.

Jordan, Kenneth Laird Ⓜ Montclair, N. J.; born in Yonkers, N. Y., Dec. 1, 1920; New York University College of Medicine, New York City, 1945; interned at St. Claire's Hospital in New York City; served a residency at the Hospital for Crippled Children in Newark, Duke Hospital in Durham, N. C., and the North Carolina Orthopedic Hospital in Gastonia, N. C.; specialist certified by the American Board of Orthopaedic Surgery; certified by the National Board of Medical Examiners; member of the American Academy of Orthopedic Surgeons; fellow of the American College of Surgeons; from 1946 to 1948 served in the Medical Corps, U. S. Naval Reserve; on the staffs of the Hospital for Crippled Children in Newark, Hasbrouck Heights (N. J.) Hospital, Mountainside Hospital, Community Hospital, and the St. Vincent's Hospital, where he died Nov. 11, aged 38.

Y.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1929; veterans of World War II; on the staffs of the South Nassau Communities Hospital in Oceanside and St. Joseph's Hospital in Far Rockaway; died in South Nassau Communities Hospital, Oceanside, Nov. 30, aged 54.

Neuhaus, Hugo Ⓜ Freeport, N. Y.; Albert-Ludwigs Universität Medizinische Fakultät, Freiburg, Baden, Germany, 1909; specialist certified by the American Board of Pediatrics; fellow of the American Academy of Pediatrics; served in the German Army during World War I; served on the staffs of South Nassau Communities Hospital in Rockville Centre and the Doctors Hospital, where he died Nov. 24, aged 74.

Nicholas, Pike Calton, Spur, Texas; Louisville (Ky.) Medical College, 1907; died in the Spur Memorial Hospital Nov. 9, aged 78.

Otradovec, Joseph Henry Marie Ⓜ Chicago; Rush Medical College, Chicago, 1901; died in the Presbyterian-St. Luke's hospital Nov. 6, aged 86.

Ott, Charles Henry Jr. Ⓜ Elmira, N. Y.; Jefferson Medical College of Philadelphia, 1920; veteran of World War I; for many years member of the board of education; member of the courtesy staff of St. Joseph's Hospital, where he died Oct. 22, aged 67.

Ovary, Stephen Francis, New York City; Long Island College Hospital, Brooklyn, 1908; died Oct. 13, aged 77.

Patterson, Job Caldwell Ⓜ Cuthbert, Ga.; born in 1892; Atlanta College of Physicians and Surgeons, 1913; member of the Southeastern Surgical Congress and the Industrial Medical Association; fellow of the International College of Surgeons and the American College of Surgeons; past-president of the Medical Association of Georgia; veteran of World War I; medical director of the Patterson Hospital; a trustee of the Andrew College; a member of the Randolph County Board of Health; county physician; a director of the Citizens Bank and of Randolph County Federal Savings & Loan Association; past-president of the Cuthbert Rotary Club; died Nov. 8, aged 67.

Parker, James Mitchell Ⓜ Portland, Maine, Harvard Medical School, Boston, 1934; served on the faculty of his alma mater; certified by the National Board of Medical Examiners; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; consultant, Webber Hospital, Biddeford; served on the staffs of the Maine Medical Center and Mercy Hospital; died in the Johns Hopkins Hospital in Baltimore Nov. 18, aged 51.

Pflueger, Edwin H. Ⓜ Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1905; died in the Hahnemann Hospital Nov. 1, aged 76.

Pharr, John Newton Ⓜ New Iberia, La.; Tulane University School of Medicine, New Orleans, 1914; died Nov. 7, aged 70.

Phillips, John William, Arcadia, Calif.; George Washington University School of Medicine, Washington, D. C., 1921; member of the American Society of Anesthesiologists, Inc.; died Oct. 28, aged 72.

Pizzi, Frederick Athanasius Ⓜ Forest Hills, N. Y.; Columbia University College of Physicians and Surgeons, New York City, 1927; fellow of the American College of Surgeons; served on the staff of the Brooklyn Hospital, where he died Nov. 21, aged 57.

Remy, Lorenzo Albert Ⓜ Chicopee Falls, Mass.; Boston University School of Medicine, 1927; medical examiner for the Fifth Hampden District; member of the staffs of the Holyoke and Providence hospitals in Holyoke; died in the Mercy Hospital, Springfield, Oct. 31, aged 59.

Richards, Clarence Alfred Ⓜ Rhinelander, Wis.; Rush Medical College, Chicago, 1902; member of the House of Delegates of the American Medical Association in 1909; served with the American Expeditionary Forces in France during World War I; formerly member of the state board of health; president of the First National Bank; once served as chief of staff of St. Mary's Hospital, where he died Nov. 14, aged 83.

Rizer, Robert Inskeep Ⓜ Wayzata, Minn.; Rush Medical College, Chicago, 1906; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the Endocrine Society; served on the faculty of the University of Minnesota Medical School in Minneapolis, where he was on the staff of the Northwestern Hospital; died Nov. 13, aged 76.

Rosenman, Jacob Daniel Ⓜ Akron, Ohio; Columbia University College of Physicians and Surgeons, New York City, 1916; died Oct. 21, aged 71.

Spiller, John Browder, Houston, Texas; University of Texas School of Medicine, Galveston, 1920; member of the Radiological Society of North America; veteran of World War I; died in the Medical Arts Hospital Oct. 31, aged 65.

Stubblebine, James Good Ⓜ Concord, Calif.; Rush Medical College, Chicago, 1936; served on the staff of the Camarillo (Calif.) State Hospital; civilian physician at the U. S. Naval Ammunition Depot; died Oct. 27, aged 63.

Thomas, Clifford Ward Ⓜ Mason City, Iowa; State University of Iowa College of Medicine, Iowa City, 1927; veteran of World War II; past-president of the Cerro Gordo County Medical Society; a member of the department of internal medicine of Park Clinic; on the staff of the Park Hospital; died Oct. 28, aged 57.

Thompson, George Farnsworth Ⓜ Chicago; Rush Medical College, Chicago, 1899; fellow of the American College of Surgeons; served on the faculty of his alma mater and the University of Illinois College of Medicine; past-president of the Chicago Surgical Society; associated with the Westlake Hospital in Melrose Park, Ill., Oak Park (Ill.) Hospital, and St. Anne's Hospital; for many years on the staff of Cook County Hospital; died Nov. 10, aged 84.

Thuringer, Joseph Marion Ⓜ Fayetteville, Ark.; Creighton University School of Medicine, Omaha, 1911; formerly on the faculty of Harvard Medical School in Boston, Tulane University School of Medicine in New Orleans, University of Oklahoma School of Medicine in Oklahoma City, and the University of Alabama School of Medicine in Mobile; retired from the Veterans Administration on July 2, 1956; died Oct. 28, aged 73.

Way, Julius, Cape May Court House, N. J.; Jefferson Medical College of Philadelphia, 1885; served as county clerk and county physician; author of "An Historical Tour of Cape May County"; died in the Burdette Tomlin Memorial Hospital Oct. 20, aged 99.

Wood, Frances Holmes, Tucson, Ariz.; New York Medical College and Hospital for Women, New York City, 1892; died Oct. 7, aged 94.

Zasly, Louis, Delray Beach, Fla.; Syracuse University College of Medicine, 1953; interned at the Queens General Hospital in Jamaica, N. Y.; served a residency at the Veterans Administration Hospital in Coral Gables; certified by the National Board of Medical Examiners; veteran of World War II; died Oct. 26, aged 33.

FOREIGN LETTERS

ECUADOR

Hepatopulmonary Amebiasis.—At a meeting of the Academia Ecuatoriana de Medicina in July, Drs. L. Arcos and J. Rodriguez of Quito reported a series of 21 patients who had amebic hepatitis with pulmonary complications. Symptoms had been present for 1 to 22 months prior to admission, with periods of exacerbation and partial remissions. Fever was present in 17 patients, but all had a dull thoracic pain radiating to the right shoulder. A productive cough with various amounts of blood in the sputum was observed in 18. Characteristically the sputum showed a uniform mixture of blood and mucus, resulting in an even pink rather than red color. This is not seen in other conditions. An enlarged and tender liver was present in 19 and dulness with fine rales at the base of the lungs was present in 15 of the patients. Roentgenograms revealed an elevation of the diaphragm and ill defined limits between liver and lungs. Pleural fluid, infiltration, and cavities with a fluid level were also frequent findings. The leukocyte counts fluctuated between 12,000 and 13,000 per cubic millimeter, never going higher, in spite of what has been reported by other observers. Endameba histolytica was found only once in the material obtained by liver puncture. It was not found in liver biopsy specimens. Treatment with emetine occasionally supplemented with chloroquine, Camoform, and antibiotics proved effective.

Diarrhea in Infancy.—At a meeting of the Academia Ecuatoriana de Medicina in December, Dr. A. Muggia of Quito reported that in a series of 379 stool cultures from infants with diarrhea pathogenic Escherichia coli were found in 40.5%. Ten serologic groups of this organism were isolated (026B6, 0127B8, 0111B4, 055B55, 0119B14, 0125B15, 0126B6, 0128B12, 086B7, and 0124B17). Of these cultures 98.5% were sensitive to kanamycin and neomycin and 56.7% were sensitive to chloramphenicol. Neomycin was found to be almost five times more effective than oxytetracycline and chloramphenicol and equally as effective as kanamycin. Diarrhea continues to be the main cause of disease and death of infants.

FRANCE

Hepatitis.—P. Mallet-Guy and co-workers (*Strasbourg méd.* 10:193, 1959) treated surgically a series of 23 patients who had chronic hepatitis and late complications of infectious hepatitis. They dissected and severed the nerve sheath surrounding the hepatic artery at the superior edge of the pancreas. This operation increased the salt and pigment contents of the bile and had a favorable effect on the glycogenetic function of the liver. The results of this periarterial neurectomy were satisfactory. Pruritus disappeared within a few hours after the operation and jaundice disappeared gradually. Cure was obtained in 16 patients. These patients' general condition was excellent when they were seen one to two years after the operation, and no dietary restrictions were required. This operation not only brought about the disappearance of jaundice but it also prevented late complications of infectious hepatitis.

Hormonal Therapy for Myocardial Infarction.—J. Bouvrain and co-workers, at a meeting of the Sociéte Médicale des Hôpitaux de Paris, reported on a series of 11 patients who had myocardial infarction and who were treated with prednisolone. Ten of these patients had had a recent myocardial infarction associated with either a state of shock or persisting fever. The other patient had had the shoulder-hand syndrome. Prednisolone was given initially in daily doses of 30 mg. by mouth. In one patient this drug was combined with hydrocortisone sodium succinate administered intravenously. This treatment caused a subsidence of fever within 24 to 48 hours in 10 of the patients, but cessation of treatment, even its gradual withdrawal, was attended by elevation of temperature in five patients between the second and the fifth day. Three patients continued to receive small doses for three weeks.

The effect on the sedimentation rate was brought about more slowly. A return to normal occurred within two weeks of treatment. In one patient who had pleuropericarditis, the pain and fever stopped within three days and the pleural effusion was rapidly reabsorbed. Diuresis with an excretion of 2 liters of urine in 24 hours was observed and was a favorable prognostic sign. Polyuria was associated in two patients with rapid disappearance of pulmonary edema, dyspnea, and roentgenologic manifestations. One unusual result of the treat-

The items in these letters are contributed by regular correspondents in the various foreign countries.

ment was observed in a patient who six weeks after the myocardial infarction suffered from scapulohumeral periarthritis and a shoulder-hand syndrome. Proteinemia was not influenced by the treatment.

GERMANY

Chemotherapy for Pulmonary Tuberculosis.—W. Schiessle and co-workers of Freiburg (*Beitr. Klin. Tuberk.* 120:255-273, 1959) reviewed the chemotherapy of pulmonary tuberculosis. In their series 231 patients were treated with amithiozone (Thiacetazone) alone; 173 with para-aminosalicylic acid (PAS) alone; 33 with amithiozone and PAS; 53 with streptomycin, PAS, and amithiozone; 101 with various combinations of amithiozone and other drugs; 70 with isoniazid alone; 182 with isoniazid in combination with other drugs but no prednisone; and 242 with isoniazid in combination with other drugs, including prednisone. The introduction of amithiozone produced a reduction in the mortality from 40 to 4%, but cavitation was little affected. Treatment with streptomycin and the various combinations of drugs produced further improvement in the results. Isoniazid represented a marked advance, but despite great advances in chemotherapy, the ideal of complete healing of fresh tuberculous cavitation can be achieved in many cases only by surgical therapy.

Vitamins in Beer.—H. Gebauer (*Pharmazie* 4:224, 1959) stated that analysis of various types of beer showed that they have a relatively high content of vitamin B. Experiments with animals showed that a definite increase in growth, confirmed statistically, resulted when they were given small quantities of beer. Microbiological assay of beer gave the following values per liter: 9 to 700 mcg. of vitamin B_1, 140 to 800 mcg. of riboflavin, 8.5 to 23 mcg. of nicotinamide, 0.6 to 2 mg. of pantothenic acid, and 180 to 1,700 mcg. of vitamin B_6. Pasteurization produces only a slight decrease in the vitamin content. The high biological value of beer is capable of improvement by further addition of vitamin B_1.

Ganglion-Blocking Drugs for Skin Diseases.—Weyer and Röhl (*Deutsches med. J.* 10:78-82, 1959) made a therapeutic test with chlorpromazine for an average of 27 days on 238 adults hospitalized because of skin diseases associated with some autonomic imbalance (neurodermatitis, acute dermatitis, eczema, psoriasis, leg ulcers with and without diffuse dermatitis, urticaria, erythroderma, and pruritis). They gave 50 mg. of the drug three times a day initially. For most patients this was combined with 25 mg. of promethazine three times a day. The tranquilizing sedative, and the doses of chlorpromazine and promethazine, which had an antipruritic effect, were found to be valuable as supplements to the usual external applications. For some patients the dose of chlorpromazine had to be increased to 75 mg. three times a day. Syncope occurred only when patients stood up contrary to doctors' orders. Tachycardia was controlled by administration of barbiturates. No definite change in the erythrocytes was observed at the end of the test. Allergic reactions to chlorpromazine did not occur. Skin testing with the two drugs used on patients who had sudden recurrences of skin diseases produced no definite results.

Labile Hypertension.—Moeller and Heyder (*Ztschr. Kreislaufforsch* 48:413, 1959), in an effort to determine whether there is any connection between a transient rise in blood pressure and essential hypertension, analyzed a series of 2,405 patients who were treated in the hospital in 1956. Of these, 1,256 (52.2%) never had a blood pressure higher than 140/90 mm. Hg during their stay in the hospital (normotensive); 663 (27.6%) showed labile hypertension, that is, their blood pressures rose temporarily above 140/90 mm. Hg, generally in the first few days, and then fell to normal without hypotensive treatment; and 486 (20.2%) had stable hypertension (blood pressure showing fluctuations above upper limit of normal). The average age of the normotensives was 38.9 years, of the patients with labile hypertension 51.1 years, and of those with stable hypertension 58.9 years.

The age difference between the groups was assumed to represent the time taken for the labile or stable stage of hypertension to develop. Thus the difference between the average age of the patients with normal tension and those with labile hypertension (12.2 years) should be considered the asymptomatic period of essential hypertension. The development of stable hypertension from labile hypertension took, on an average, 7.8 years. This means that the course of essential hypertension, including the latent period, may be reckoned as about 20 years. The duration of the latent period may be affected by various conditions. The onset of labile hypertension may be provoked or delayed, but the total duration of the condition seems to be closely related to age. This is in accordance with the findings of Wollheim that essential hypertension is not an acquired but a constitutional disease, in which exogenous factors only determine the time of onset of clinical manifestations.

Quinine Oxydase in Diagnosis of Hepatic Disease.—H. Baier of Mainz (*Deutsche med. Wchnschr.* 84:1308-1312, 1959) stated that estimation of various serum enzyme activities is being increasingly used as a method of diagnosing liver diseases. Apart from esterases, glycolytic enzymes, especially those of the tricarboxylic acid cycle, are predominantly used. Recently the presence of quinine oxydase has been discovered in the serum of patients with hepatic disease. This enzyme is never present in normal persons or in patients with autonomic disturbances, renal disease, arteriosclerosis, or compensated cardiac disease. The critical quantity is 4 or 5 units. In patients with hepatitis the serum quinine oxydase (ChO) level indicates more exactly the degree of damage to the parenchymal liver cells than does the serum bilirubin or the serum glutamic oxalacetic transaminase (SGO-T) level, which has hitherto been generally used.

The latter fact is evident in patients with hepatitis of prolonged duration, in whom the SGO-T levels remain fairly constant, whereas the ChO level reflects every fluctuation in the course of the disease. In patients with obstructive jaundice the enzyme is absent, or present in very low concentration. If parenchymal damage occurs during obstruction the ChO level rises, but in this case the graph of the level is always a straight line, whereas in cases of hepatitis it rises to a peak and then falls. In secondary carcinoma of the liver, cholangitis, hepatic congestion, or other diseases which affect the liver incidentally, the ChO level rises in proportion to the degree or amount of damage to the liver parenchyma. In cirrhosis, the ChO level rises moderately and reaches a peak only when a fresh exacerbation of the condition occurs. Giving cortisone to patients with hepatitis causes the markedly raised ChO level to fall rapidly almost to normal, a result which can be explained only by the vasoconstrictor effect of cortisone. Quinine oxydase has the advantage, which it shares with l-phosphofructaldolase alone, of being demonstrable in the serum only if there is damage to the liver, whereas the other enzyme levels are either raised in other diseases or are normally present in serum.

Erythroderma Desquamativa.—Eckhardt and Kunad (*Kinderarztl. Praxis* 26:443-451, 1959) stated that the pathogenesis of erythroderma desquamativa is still obscure. In 95% of a series of 160 patients with this disease the onset occurred during the first three months of life. The fatality rate for this group was about 5%, much less than that observed by Lust and Pfaundler (20 to 30%). Good results were obtained with bran baths and boric acid ointment. Apart from a bland diet (ground rice and buttermilk) with vitamin supplements phenothiazine, crude liver extract, methionine, and cortisone were given. Follow-up examinations showed no evidence of a tendency to an exudative diathesis or to bronchitis and asthma.

Indications for Resection in Pulmonary Tuberculosis.—Krann and Eerland (*Beitr. Klin. Tuberk.* 119:499-515, 1959) reviewed a series of 1,496 resections performed for pulmonary tuberculosis between 1943 and 1957 (inclusive). The percentage of segmental resections rose to 84.2% while the number of pneumonectomies and lobectomies fell to 1.4% and 14.4% respectively. In the period after 1950 more than 55% of the patients showed cavitation when they were admitted. More than 70% of those who were discharged recovered after resting in bed and receiving medical treatment. At present the main indication of the need for resection is the presence of a tuberculous focus that persists unchanged in a patient who has stayed in bed and received chemotherapy over a 7-to-10-month period and who still has infected sputum and shows signs of imminent or actual development of bacterial resistance.

Follow-up investigations on those patients who were operated on showed that the primary mortality after pneumonectomy was 8%, after segmental resection 0.25%, and after combined lobectomy and segmental resection 0.6%. Preoperative and postoperative measures have undergone a marked change. In order to reduce the risk of the development of resistant strains, the right moment must be chosen for excision of the main focus. Complications included bronchial fistulas (4%) and recurrences (5.7%). After operation the results of sputum tests became negative in 97.6% of the patients, and 89.6% became completely fit for work. Of 637 patients who were followed up for more than five years, 98.1% had normal sputum and 93.8% were fit for work. Thoracoplasty was performed on some patients as a preliminary measure. There is virtually no use for intrapleural or extrapleural pneumothorax, and operations on the phrenic nerve have become obsolete.

Nontuberculous Pathogenic Mycobacteria.—G. Lebek (*Deutsche med. Wchnschr.* 13:33-36, 1959) stated that acid-fast bacilli which are not Mycobacterium tuberculosis may produce a disease similar to pulmonary tuberculosis. Lymphadenopathies in childhood that are grossly and histologically indistinguishable from tuberculosis may be produced by pathogenic mycobacteria which are not tubercle bacilli. Patients with the pulmonary form of this disease often have a dry cough but generally feel well and have no fever. Apart from this they present all the symptoms of tuberculosis. Stained by Ziehl-Neelsen's method, the organisms look like tubercle bacilli. Incubation on egg culture medium for two or three weeks gives yellow-orange colonies with a sharp edge and smooth surface. Many strains form pigment only on exposure to light. Furthermore many strains are resistant to the usual tuberculostatic drugs. They are generally pathogenic for mice and hamsters but not for guinea pigs, rabbits, and chickens. To date acute forms of the disease are unknown. The treatment of choice seems to be resection. The organisms have a low level of infectivity. It is, therefore, highly desirable that examination of cultures be made much more frequently than hitherto.

Other mycobacteria have been found which are also pathogenic to man but which are distinguishable from Myco. tuberculosis. Mycobacterium ulcerans, which gives rise to skin lesions, is one of these. It has been isolated from smears from the cement walls and the water of a fish pond. Carriers of such organisms should be separately isolated if they are treated in tuberculosis hospitals so that they do not become superinfected with tuberculosis.

INDIA

Gastric Phosphatase Activity in Cancer of the Stomach.—Ambaye and Talavdekar (*Indian J. M. Res.* 47:5 [Sept.] 1959) stated that estimations of serum acid and alkaline phosphatase levels have proved helpful in the diagnosis and prognosis of metastatic cancer of the prostate and that serum alkaline phosphatase is effective in diagnosing malignant bone tumors. Both enzymes are present in the gastric mucosa. The authors studied changes in phosphatase activity in gastric mucosa associated with malignant changes in order to observe whether these were reflected in the phosphatase activity of the gastric juice. A series of 175 randomly selected patients with various kinds of gastrointestinal disease was studied; 17 of these had histologically proved gastric carcinoma.

Studies on gastric juice showed an overlapping of values in patients with and without cancer. Four of the 17 patients with cancer showed an increase in alkaline and acid phosphatase activity and 10 showed increased alkaline phosphatase activity alone. Patients with and without cancer who had little or no phosphatase activity in the gastric juice had some free acid in the fasting sample, and those with increased phosphatase activity had achlorhydria. The increased alkaline and acid phosphatase activity seen in a few patients with normal, hyperchlorhydric, or hypochlorhydric findings after the test meal could be attributed to the absence of free acid noted in the fasting sample. Of 37 patients with achlorhydria, 30 had a raised alkaline phosphatase level and 19 had increased acid phosphatase activity. Results on achlorhydric patients were statistically significant as compared to those obtained with hyperchlorhydric, normal, or hypochlorhydric patients.

Thus the increased phosphatase activity seen in some cancer patients could be explained on the basis of achlorhydria and could not be regarded as a reliable index of malignancy of the stomach. Results of studies on normal and neoplastic gastric mucosa showed a significant increase in the alkaline phosphatase activity and a moderate increase in the acid phosphatase activity in patients with adenocarcinoma as compared to the values obtained in the adjoining uninvolved mucosa. This difference was statistically significant. The authors concluded that the changes in phosphatase activity occurring in the gastric mucosa and associated with malignancy were not truly represented by the phosphatase activity of the gastric juice. This may be due to its variable acidity and its complex composition. The phosphatase activity of the gastric juice is therefore of no diagnostic value in malignancy of the stomach.

Cholera.—*The Bulletin of the Calcutta School of Tropical Medicine* (vol. 7, no. 4, October, 1959) reported that chloramphenicol was given to a series of 79 patients with cholera. Because good results have been reported elsewhere from the use of vitamin C and antihistaminics in the treatment of uremia associated with cholera, these were also given. Fifteen patients received chloramphenicol by mouth in a total dosage of 4 Gm. in two days, and 64 received the drug intravenously in a dosage of 1 to 1.5 Gm. within 15 to 18 hours of admission. Another group of 64 patients served as controls. Stools were cultured daily. Rapid disappearance of vibrios from stools was noticed after administration of chloramphenicol by either means, the stools being vibrio-free in 48 hours. In the control group the vibrios persisted for a longer period. No adverse effects were noticed with the dosage used.

The administration of chloramphenicol did not alter the clinical course of the disease, the only difference being in the earlier disappearance of vibrios from stools in the treated group, an effect which may be important for public health. The use of vitamin C and antihistaminics did not prevent uremia, and if it developed these drugs did not promote recovery. Two types of renal damage resulted from the dehydration produced in this disease. In the first, which was reversible and was observed in most patients, functional disturbances followed a sharp fall of blood pressure and were due to renal ischemia. These patients recovered, with restoration of normal circulation. The second type was irreversible and occurred in the stage of initial shock.

Biochemical studies showed that there was little change in the initial plasma sodium and chloride level, but the initial potassium level, which was usually high, became subnormal after treatment. In view of these findings, isotonic saline solution is the ideal infusion for replacement of both fluid and salt. The degree of dehydration could be judged accurately from changes in specific gravity of the plasma. This change is mainly due to loss of fluid and should be corrected by giving normal saline solution.

Reduced Fare for Some Patients.—Patients with tuberculosis or cancer can now travel by rail for one-fourth of the normal fare to and from a hospital, sanatorium, or clinic for reexamination or a periodic check-up. Until now this reduction was available only for journeys undertaken for admission to or discharge from a hospital or sanatorium. The new concession provides that when a patient is accompanied by an attendant both parties may travel round trip on payment of a single one-way fare. Tuberculous patients can avail themselves of this reduced rate only within the state in which they reside, but no such restriction applies to patients with cancer.

UNITED KINGDOM

Maternal Influenza and Congenital Deformities.—In an investigation into the incidence of congenital deformities in Dublin, Coffey and Jessop noted that 18.4% of the mothers of abnormal babies had had influenza, but there was no epidemiologic or laboratory evidence to confirm the diagnosis. Another opportunity occurred to investigate the possible relation of maternal influenza to fetal deformities during the epidemic of Asian influenza (*Lancet* 2:935, 1959). As the onset of the epidemic was foreseen, plans for the study were prepared in advance. All women attending the antenatal clinic of Dublin's three maternity hospitals were interrogated.

There were 663 who had Asian influenza at some time during their pregnancy, and virus A was isolated in all of them by the public health authorities. These women were matched for age, parity, and ABO and Rh blood groups with pregnant women who had not had influenza. The infants born to all the women were carefully examined for congenital abnormalities, in particular, anencephaly, spina bifida, meningocele, encephalocele, hydrocephalus, and mongolism. The incidence of these in children born to women who had Asian influenza during their pregnancy was almost two and one-half times that in the control group. The anomalies were almost entirely in the central nervous system, anencephaly being the commonest. Prematurity was higher in the infants of mothers who had influenza during pregnancy, but the incidence of stillbirths was the same in the two groups. The sex of the infants was not affected by the mother's influenza.

As with rubella, the incidence of congenital malformations in the offspring of influenza victims was greater when the infection occurred in the first trimester of pregnancy. It was 7.4% in the first trimester, 4.3% in the second, and 2.0% in the third. While these figures are lower than for rubella they are serious because influenza epidemics are so common. Coffey and Jessop suggested the advisability of offering pregnant women vaccination against influenza when an epidemic is in progress or pending.

Transventricular Valvotomy.—The atrial approach to the operation of valvotomy for the surgical treatment of mitral stenosis has been widely practiced for about 12 years. The ventricular approach to the mitral valve had been suggested, but the superiority of the atrial over the ventricular route remained undisputed for several years until Logan and Turner introduced the transventricular approach to the mitral valve, which they split with a mechanical dilator. These surgeons have now reviewed their work of the last five years on 438 patients on whom this approach, which has now been widely adopted, was used (*Lancet* 2:784, 1959). The authors found that transventricular valvotomy with a dilator is quicker and more thorough than digital dilatation, even in the presence of severe calcification, with the result that the number of patients in whom division of both commissures was incomplete dropped from 26 to 11%. The rapidity of the method helped to prevent occlusion of the stenotic orifice for all but the briefest interval, and the heart was handled less because of the brevity of the procedure. There was also less risk of dislodging emboli in the atrium. The use of a stop on the dilator caused the dilatation to be gradual and thus prevented sudden rupture of the valve. The rupture occurred at the weakest point, that is, along the commissures. The dilator provided its own counterpressure, so that at no time was there any dragging on the heart. The risk of traumatic mitral incompetence was no greater than with the use of the atrial approach.

At any rate the proportion of deaths from this cause was substantially the same in both methods. The death rate in Logan and Turner's transventricular series was only 5%. It had been 6.4% in a previous transatrial series of theirs. Other advantages claimed for the transventricular operation were a more effective opening of the valve and better postoperative results. Calcification of the valve was no obstacle to the operation and was not associated with a higher mortality. The figures for cerebral embolism were slightly lower than after the atrial operation. Ventricular fibrillation was not a problem. Logan and Turner concluded that the transventricular approach and the use of a mechanical dilator was a valuable addition to the technique of mitral valvotomy.

CORRESPONDENCE

PRACTICE OF FLUID THERAPY

To the Editor:—In the article entitled "Practice of Fluid Therapy," appearing in THE JOURNAL, Sept. 5, page 131, certain statements merit discussion. With regard to rates of use of dextrose administered intravenously, the author states, "The latter is probably less than 0.3 Gm. of dextrose per kilogram of body weight per hour in the starved subject because of 'starvation diabetes'. In the hydrated, nonstarved subject, a safe figure is probably less than 0.5 or 0.6 Gm. per kilogram of body weight per hour." Wilder and Sansum (*Arch. Int. Med.* 19:311 [Feb. 17] 1917) showed that the tolerance limit of normal men and women for dextrose administered intravenously is practically constant and at a rate of about 0.85 Gm. per kilogram of body weight per hour. This is at variance with the figure of 0.5 or 0.6 Gm. given by the author.

As far as starvation diabetes is concerned, it has been demonstrated by many investigators that in normal subjects who have either been starved, kept on a low-carbohydrate diet, or kept on a diet high in fat, a diabetic type of curve may be obtained after the usual dose of dextrose is given (Sweeney: *Arch. Int. Med.* 40:818 [Dec.] 1927). It must be emphasized, however, that the elevation of the blood sugar curve is slight, indicating only a small reduction in dextrose tolerance. The conclusion may be drawn that normal persons can tolerate an infusion rate of 0.85 Gm. of dextrose per kilogram of body weight per hour. In a case in which there is a history of starvation for several days or a diet markedly deficient in both protein and carbohydrate, the maximum infusion rate is 0.7 Gm.

With regard to water balance, the author states that estimations of change in the quantity of body water are best and most accurately made by serial (usually daily) measurements of body weight. He assumes for purposes of fluid therapy that the range of daily loss of body weight as a result of negative caloric balance is about 0.1 to 0.4 kg. (4 to 14 oz.). He interprets any marked loss in weight above 0.4 kg. per day as indicating a deficiency of body water content.

The author has not taken cognizance of two important physiological principles. 1. After a subtotal gastrectomy, male patients who were maintained solely on dextrose solutions given intravenously during the postoperative period showed a five-day cumulative nitrogen deficiency of 60 Gm. and lost about 0.5 kg. (1 lb.) of body weight per day (editorial, *J. A. M. A.* 165:1830 [Dec. 7] 1957). Protein cannot be stored dry but retains with it three or more parts of water. Thus the catabolism of the 375 Gm. of endogenous protein (60 Gm. of nitrogen) resulted in the excretion of 1,125 cc. of water, with a loss of 1.13 kg. (2.5 lb.) of body weight. The loss of the 1.13 kg. of water did not in the slightest affect the water balance of the body. 2. When a patient is in negative caloric balance he does not necessarily lose weight every day. Many observers have emphasized that the curve of daily weight change is a series of ups and downs, with frequent periods of no apparent weight change. As has been repeatedly demonstrated, these irregularities are intimately associated with the storage and release of relatively large quantities of water (Newburgh and Johnston: *Ann. Int. Med.* 3:815 [Feb.] 1930). A sudden drop in weight, therefore, does not necessarily indicate that a negative water balance has developed; it may be the result of the sudden release of stored water. It may be concluded that serial daily weight measurement, as an index of water balance, is not valid in a patient with marked negative nitrogen and caloric balances.

How, then, is one to correct the marked negative water balances which result from severe diarrhea, sweating, vomiting, and loss of fluid from draining fistulas? The capacity of a normal person to tolerate parenterally administered fluid is enormous. Thus, Root and Riseman (*J. A. M. A.* 110:1730 [May 21] 1938), gave to two patients who were suffering from diabetic coma 13,800 cc. (13.8 kg. or 29.4 lb.) and 11,600 cc. of total fluid, respectively, during the first 29 hours of treatment. No sign of cardiac failure was seen in either patient. Both were fundamentally normal as regards the cardiovascular-renal system. In patients who suffer large water losses, 5 to 7 liters may be given. Recourse to weighing is unnecessary, nor need there be any concern about the diuretic action of any sugar that may spill over. Nitrogen deficit is inversely proportional to the total caloric intake. One should, therefore, give the maximum amount of dextrose in order to reduce the negative nitrogen balance.

MAX WISHNOFSKY, M.D.
615 Williams Ave.
Brooklyn 7, N. Y.

This item was referred to the author of the original article, whose reply follows.

To the Editor:—An intent of my paper was to provide rules of thumb regarding rates of dextrose infusion and interpretations of accurate serial body weights. All rules of thumb (by definition designed for average or common situations) do not take into account several contingencies. Some of these contingencies appear to be partially considered in Dr. Wishnofsky's comments.

Several investigators (references in next paragraph) extended pioneer studies (Woodyatt and others: *J. A. M. A.* 65:2067, 1915; Wilder and Sansum: *Arch. Int. Med.* 19:311 [Feb. 17] 1917) of rates of use of intravenously given dextrose in patients who require parenterally given fluids. These investigations established the variability of these rates. This variability has been confirmed by my own experience and data as well as by those of other students of fluid therapy. Occasionally nondiabetics develop significant hyperglycemia and glycosuria even with rates of infusion below 0.3 Gm. of dextrose per kilogram per hour, whereas others use practically all the dextrose given at rates of 1 Gm. or more per kilogram per hour.

One important factor which appears to account for a low rate of dextrose utilization is starvation. Thus, dextrose given intravenously at rates exceeding 0.2 or 0.3 Gm. per kilogram per hour may produce hyperglycemia and glycosuria during starvation (Winslow: *Surgery* 4:867 [Dec.] 1938; Pareira and Probstein: *Ann. Surg.* 133:299 [March] 1951). After starvation is partially corrected by the patient's use of 20 to 50 Gm. of dextrose (Pareira and Somogyi: *Ann. Surg.* 127:417 [March] 1948), an increase in rate to less than 0.5 or 0.6 Gm. per kilogram per hour will usually be tolerated. On the other hand, some patients will not tolerate this increment (Wilder and Sansum; Elman and others: *Ann. Surg.* 130:703 [Oct.] 1949; Lockhart and Elman: *Surg., Gynec. & Obst.* 88:97 [Jan.] 1949), whereas other patients can tolerate even greater increments (Wilder and Sansum; Winslow; Pareira and Somogyi; Lockhart and Elman).

Ideally, these problems are best solved by considering each patient individually and frequently estimating urinary and blood sugar levels. Short of this, reliance should be placed on such rules of thumb as I have proffered—but with full realization that exceptions to these rules do occur. Moreover, the need for an infusion rate exceeding 720 ml. of 5% dextrose solution per hour for a patient weighing 60 kg. (132 lb.) is exceptional (this rate corresponds to 0.6 Gm. of dextrose per kilogram per hour), and when this exceptional need does arise it can be met with use of more dilute solutions of dextrose plus sufficient sodium or other appropriate salts to make an isotonic solution.

Blood sugar concentrations in nondiabetics occasionally rise to values similar to those in patients with uncontrolled diabetes mellitus, as a result of excessive dextrose loading, particularly during starvation (Sweeney: *Arch. Int. Med.* 40:818 [Dec.] 1927; Conn: *Am. J. M. Sc.* 199:555 [April] 1940). Although the deleterious consequences of glycosuria, in terms of water diuresis and increased excretion of sodium chloride in already depleted patients, are well known, the fact that hyperglycemia probably entails ill-effects in itself because of its tendency to increase the osmolarity of the extracellular fluid is less well known (Seldin and Tarail: *J. Clin. Invest.* 29:552 [May] 1950; *Am. J. Physiol.* 159:160 [Oct.] 1949). This increase in osmotic pressure may then be reflected in withdrawal of water from the cells and intracellular dehydration. Proportionate dilution of extracellular fluid and reduction in the concentration of serum sodium also ensue.

The validity of my statements about serial measurement of body weight as a useful, although neglected, index of change in body water still stands. A precise correlation between serial body weight changes and changes in water balance was recently demonstrated (Paquin and others: *Metabolism* 8:16 [Jan.] 1959). This precise reflection of changes in body water content by weight measurements was observed in eight patients undergoing major gastrointestinal or genitourinary operations, irrespective of positive or negative nitrogen balance. This, and previous studies by the same group, establishes the fact that serial body weights define changes in body water content if one "corrects" for tissue loss, which comes to about 5 Gm. per kilogram per day.

My proposals in relation to serial body weights correspond closely to the opinions and data of numerous observers over the years (Newburgh and Johnston: *Ann. Int. Med.* 3:815 [Feb.] 1930; Wangensteen: *New England J. Med.* 236:121 [Jan. 23] 1947; Dieckmann and Stout: *Am. J. Obst. & Gynec.* 59:1021 [May] 1950; Moore and others: *Ann. Surg.* 141:145 [Feb.] 1955). The work of Newburgh and Johnston is particularly pertinent, because it is quoted by Dr. Wishnofsky. It is one of the early clearcut demonstrations of a close relation between body weight change and change in water balance.

Finally, a moment's reflective thinking defines certain areas in which body weight measurements are important. For example, loss of 3 liters of sweat in 24 hours will reflect itself in a loss of about 3 kg. (6.6 lb.) of weight, unless this loss has been replaced. Similarly, loss of 3 liters of unmeasured or unmeasurable fistulous, diarrheal, or other gastrointestinal fluid over 24 hours will, unless it is replaced, reflect itself in the loss of about 3 kg. in weight.

TOLBUTAMIDE

To the Editor:—I read with interest the article in The Journal, Nov. 28, 1959, page 1786, by DeLawter and co-workers. With their large group of diabetic patients, they experienced an attrition rate of 3% per month of secondary delayed failure of tolbutamide therapy after an initial success. This will come as a surprise to those who, like myself, have participated in the use of this drug from the time of its introduction in 1955. Most such patients are still amenable to treatment. The authors' findings represent an even more conspicuous discrepancy from the experience of European clinicians who have used the sulfonylureas to treat a larger group of diabetic patients for an even longer time, with a reported incidence of true secondary failure of less than 10%. Since the unwary reader might draw an unwarranted conclusion about the expected result of therapy with the sulfonylurea drugs, this unique variance from general experience deserves to be reexamined critically.

The singular experience of these workers could not be attributed to the natural progress of the disease nor to an unsual degree of dietary disregard, high even for a group of clinic patients, since the average insulin requirements of their patients after discontinuance of sulfonylurea therapy was equal to pretherapy requirements. Examination of their data, however, shows that the criteria for initial success were extremely liberal. This would have been more obvious if postprandial instead of fasting blood sugar levels had been used as the index of success. As a result, most of their patients who had good or fair success could have been reclassified as having primary failures. This is especially true in the face of such severe (judged by insulin requirements) diabetes, particularly if the classification had been made a relatively short time after starting therapy. Under such experimental conditions, secondary failure would be an inevitable outcome, given enough time. Such a significant therapeutic deficit in a group of moderately severe diabetics could lead to metabolic decompensation, with rising blood sugar levels after weeks to months and not necessarily immediately.

If, as seems probable, the above results were due to the special experimental circumstances of the study, they should not be used as a basis for general conclusions about the long-term outlook of sulfonylurea therapy in patients with diabetes without further confirmation. This is important, since the average physician treating diabetes must remain alert to possible dietary infractions and the natural progress of the disease, when evaluating therapeutic results by any means, and it would be preferable not to have his attention diverted by unwarranted or unnecessary pharmacological doubts.

THERAPEUTIC NIHILISM

To the Editor:—The "Primer on Rheumatic Diseases" which appeared in The Journal in October and November, 1959, must again be accorded a warm reception, covering as it does a broad field in such a superior manner. In an effort to contribute to the comprehensive and authoritative design which seems to prevail in this series, I should like to comment on a number of statements about the therapy of collagen diseases, which, if left unchallenged, might seem to support a pessimistic attitude toward the management of some of these diseases.

The discussion on polyarteritis nodosa, under the section on treatment (*J. A. M. A.* 171:1355 [Nov. 7] 1959), begins with the statement "No specific therapy is known." Again, the section on the treatment of dermatomyositis starts with the words, "Therapy is largely symptomatic." Both discussions of treatment include qualified statements concerning the virtues of corticosteroids in therapy. Judging by the literature, therapy of dermatomyositis with corticosteroids has been of value in only a few patients so treated. Yet, as the Primer states, enough instances of striking improvement have occurred to justify their continued use. Pollock reported a patient with dermatomyositis in whom ethylenediamine tetraacetic acid sodium was used with apparent benefit (*California Med.* 90:284 [April] 1959) and Zarafonetis (*Texas J. Med.* 49:666 [Sept.] 1953) reported a series of patients who improved significantly while treated with potassium para-aminobenzoate.

In polyarteritis nodosa the picture appears somewhat brighter. Schick (*M. Clin. North America* 42:959 [July] 1958), reported a series of 50 patients treated with corticosteroids, on 30 of whom follow-up data were available. In 21 of these the disease appeared to be in remission or adequately suppressed when they were last seen. A series of three children who responded well to treatment with cortisone or ACTH was reported by Yonis (*Ann. paediat.* 192:65 [Feb.] 1959; abstracted in *J. A. M. A.* 170:1476 [July 18] 1959). A series of patients treated with cortisone as reported to the British Medical Research Council (abstracted, *J. A. M. A.* 164:922 [June 22] 1957) appeared to do much better than a control group. Another optimistic report was abstracted in The Journal (165:1319 [Nov. 9] 1957).

As for scleroderma the Primer states that no specific remedies have appeared to be of consistent value in the treatment of this disease. By and large, this is true, yet, to accept this statement without reservations would be to deny some patients benefits which have been reported after specific therapy for specially selected patients with scleroderma. Talbott and Moleres Ferrandis (Collagen Diseases, Grune and Stratton, New York, 1956, p. 176) in discussing the treatment of scleroderma give much credit to steroids for the symptomatic benefit they produce. Winkelmann (*Proc. Staff Meet. Mayo Clin.* 34:55 [Feb. 4] 1959) found that relaxin, chelating agents, and steroids produced some beneficial effects in selected patients with scleroderma, effects which in some patients were transient and in others difficult to evaluate. Another agent considered effective in the treatment of this disease is potassium para-aminobenzoate, as reported by Zarafonetis (*Ann. Int. Med.* 50:343 [Feb.] 1959; *Texas J. Med.* 49:666 [Sept.] 1953).

Thus, granted that there are various limitations and reports of failures in treatment, nevertheless, a variety of agents is available for therapy of the diseases mentioned, and these are effective enough to justify the maintenance of an expectant, rather than a pessimistic, attitude toward the results of treatment.

SUM RITIN

Dear Mr. Editur:—jest read a peice of Dr. Sam's riting [Garlan, S. A.: Rebirth of General Practice, *J. A. M. A.* 171:1941 (Dec. 5) 1959.] in last weaks Journal bout doctoring in the wilds of Montana. I kinda took it to hart cause I'm one of them there Doc's that confines my doctoring to what you Eastern fellas call Internal Medicine. Thought you might like to know, Dr. Sam, that we also have Docs that kinda confine their doctoring to kids, delivering babies, broken bones, cutting, and even nerves. A right good number of these Docs, Dr. Sam, have had the gumption to leave the old homestead to take and pass some of those Eastern Board Exams. These Docs do a right proud job of doctoring and sure do see a heap of folks. We have a good many General Docs out here too and they're right nice fellas and do an awful good job. Hope these few remarks kinda clear the air, Partner. Much obliged.

E. J. Scherba, M.D.
110 Neill Ave.
Helena, Mont.

P. S. Woulda rote more, Dr. Sam, but have to go down the road a peice and give a dose of salts to a case of alpha 3-Globulinemia. If you have any idees on this here condition I would surre be tickled pink to here from you. Please stop by and meet ma and the younguns if you ever visit Montana.

The invitation is appreciated.—Ed.

COLLECTING BOTTLE FOR T-TUBES IN AMBULANT PATIENTS

To the Editor:—I am sure most surgeons who perform common bile duct surgery have had difficulty obtaining a satisfactory collecting bottle for the T-tube in an ambulant patient. For the past four years I have been using a Fleets enema bottle and it has given better results than any other type of bottle I have ever used. I usually have the nurses empty the bottle and give the enema solution to any patient who may need an enema. This leaves an excellent collecting bottle to attach to the end of the T-tube and tie on to the dressing or binder. It has the advantages that (1) the enema tip will accommodate almost any size of T-tube, (2) it is plastic and will not break, (3) it is soft and comfortable for the patient, (4) it is not as heavy as an ordinary glass bottle, and (5) the top remains tight, yet it is easily removed for cleaning.

CARPAL TUNNEL SYNDROME

To the Editor:—In The Journal, Nov. 14, page 1625, in Questions and Answers, there is an inquiry about the carpal tunnel syndrome. The question posed was that of the relationship of carpal tunnel syndrome to systemic diseases. The answer to this question was misleading. An article entitled "Systemic Disease and the Carpal Tunnel Syndrome" by Grokoest and myself that appeared in The Journal, June 12, 1954, page 635, should answer Dr. Jabush's question.

Felix E. Demartini, M.D.
620 W. 168th St.
New York 32.

To the Editor:—I would like to comment on the question submitted by Dr. Jabush on the association of carpal tunnel syndrome to systemic disease, appearing in Questions and Answers in The Journal, Nov. 14, 1959. I disagree with the answer that systemic disease is not found in patients exhibiting this syndrome. In a personally studied case (with Dr. William Dameshek), the syndrome appeared in a patient who had had multiple myeloma for about two and one-half years. The median nerve compression was relieved neurosurgically. At the time of the operation material removed from the patient's wrist was found to be "amyloid." While I do not have the exact reference to this association, I do recall an abstract which appeared in *Modern Medicine*, probably in 1957, in which several patients with amyloidosis, both primary and secondary, in whom carpal tunnel syndrome was present, were described.

I am pleased to discover that Questions and Answers are widely read.—Ed.

MEDICAL FILM REVIEWS

Technique with the Fresh Temporal Bone: 16 mm., color, sound, showing time 17 minutes. Prepared in 1958 by Harold F. Schuknecht, M.D., Detroit. Procurable on loan (service charge $3) from Motion Picture Library, American Medical Association, 535 N. Dearborn St., Chicago 10.

In the technique shown at autopsy, the oscillating circular Stryker saw is used. The brain is removed first and then the bone plug cutter, 1.5 in. in size for the adult, is centered on the arcuate eminence. After the bone plug has penetrated the base of the skull, the plug is grasped with bone forceps and removed. If the specimens are to be used for future anatomic-surgical dissection, they may be preserved by refrigeration. The fresh state may be preserved for many months by placing the specimens in moist cotton, wrapping them in freezer paper, and placing them in a deep freezer. For anatomic-surgical dissection, the temporal bones are placed in a special temporal bone holder which consists of a heavy hemispherical bowl held in a stand which permits it to be tilted. If the temporal bones are acquired from a person having deafness or vertigo, they are placed in fixative immediately and then decalcified, embedded in celloidin, and serially sectioned. The acquisition of fresh human temporal bones is essential to otological training and research programs. This is an excellent teaching film. The technique shown is an improvement on the older methods of removing the temporal bone, both from the point of view of ease of removal and the fact that this technique does not increase the technical problems of the mortician or affect the external appearance of the body. This film is recommended for otolaryngologists, residents, and pathologists who may be interested in removing temporal bones at autopsy for histological study or in anatomic dissections.

Technique of Biceps Cineplasty: 16 mm., color, sound, showing time 30 minutes. Produced in 1958 by and procurable on loan from Walter Reed Army Institute of Research, Walter Reed Army Medical Center, Washington 12, D. C.

This is an excellent film on the operative technique of biceps cineplasty. It goes into minute detail of the meticulous surgical technique used in this procedure. Positioning of the patient, positioning and outlining the flap, and dissection are illustrated. The flap is folded into a tube and drawn through the tunnel in the perforated biceps muscle, the corners are closed, and the defect is covered with a split-thickness graft. The progress of the wound healing and the physical therapy program for developing the biceps muscle are shown. Also demonstrated is the training program in the use of prostheses. Rehabilitation is aimed at development of use of the prosthetic hook and hand in everyday activities. The photography of the surgical technique is good. Narration is clear, with ample explanation of the demonstrations. Postoperative scenes are used effectively. The film will be of particular value to the general and orthopedic surgeon who deals with the amputee.

NEW FILM ADDED TO A. M. A. MOTION PICTURE LIBRARY

Medifilm Report of the 13th Annual Clinical Meeting: American Medical Association, December 1-4, 1959, Dallas, Texas: 16 mm., black and white, sound, showing time 25 minutes. Presented by the American Medical Association and Schering Corporation. Produced in 1959 by Fordel Films, Inc., New York. Procurable on loan (no service charge) from Motion Picture Library, American Medical Association, 535 N. Dearborn St., Chicago 10, and Audio Visual Department, Schering Corporation, Bloomfield, New Jersey.

This film was prepared as a service to physicians who were unable to attend the meeting. Physician interviews, panel discussions, special guest lectures, and scientific exhibits are featured in this documentary film. J. S. Chapman, member of the Dallas County Medical Society, host organization, is narrator. Some selected highlights of the meeting include an interview with H. Strughold, professor of space medicine, Randolph Air Force Base, Texas; a discussion by S. G. Wolf on use and abuse of tranquilizers and their role in psychiatric care; a panel discussion on treatment of rheumatoid arthritis with W. P. Holbrook, chairman, M. Ziff, C. J. Smyth, and W. S. Clark; and an illustrated lecture by O. Auerbach concerning his recent findings on the trachea and bronchi of smokers. The narrator interviews various exhibitors as the camera focuses on their scientific exhibits. B. E. McLaughlin discusses emotional disturbances; J. Q. Gant Jr. points up aspects of his exhibit on griseofulvin in ringworm infections; N. O. Rothermich explains use of latex fixation tests for rheumatoid arthritis; and E. L. Becker discusses the use of percutaneous renal biopsy in establishing tissue diagnosis of nephrotic syndromes in adults and presents a brief outline of treatment procedures.

Typical Dallas scenes provide a colorful background. The film offers a dramatic sampling of convention highlights and a glimpse of the convention city, giving the viewer a sense of participation. It summarizes some outstanding scientific subjects which were presented and discussed before a large group of inquiring physicians. The photography and sound recording in this film are well done, and it is highly recommended to state and county medical societies, hospital staffs, and individual practitioners. Medical students, interns, and residents will also find items of interest.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Unexplained Heart Failure in the Aged. G. A. Rose and R. R. Wilson. Brit. Heart J. 21:511-517 (Oct.) 1959 [London].

When older persons die of heart failure, the clinician generally assumes that myocardial ischemia is a factor, but sometimes the pathologist can neither confirm this diagnosis nor suggest any other adequate explanation. The authors collected data on such cases in the hope of clarifying their etiology. Their study was based retrospectively on 50 consecutive autopsies on patients who died, at an age of 70 years or more, of heart failure for which the clinician could find no adequate explanation. A proper assessment of the importance of various common conditions—hypertension, coronary disease, and brown atrophy, for example—required some standard by which to estimate their general incidence in the elderly. Each heart failure subject was, therefore, matched by the next person of the same sex and age (± 3 years) who came to autopsy without evidence of heart failure, and also without any of the clinical conditions specified earlier as possible causes of heart failure.

It was found that chronic failure of a structurally normal heart was common, and the authors do not consider it unreasonable to postulate that they may be dealing with a myocardium that has been weakened through some process connected with age itself. The pathologist, by examination of the heart alone, cannot tell whether a patient has died of heart failure. Campbell has taught for years that he cannot distinguish between 2 large hearts, both from patients with hypertension, one of whom has died after a road accident and the other after congestive failure. Inasmuch as one is already familiar in the aged with the paradox of failure of the mind and weakening of the limbs which are not reflected after death in any visible change in the brain or muscles, a similar obscure weakening may also affect the myocardium. Nevertheless, such a hypothesis must not be too readily adopted, lest it hide some cause of myocardial failure more specific than mere senility.

On the basis of the autopsy findings, the authors feel that their patients can probably be divided into 3 etiological groups: (1) those with former hypertension; (2) those with occult myocardial ischemia; and (3) those with normal blood pressures and with hearts of normal appearance. This last entity can perhaps be referred to as "senile heart failure," provided one recognizes that the term "senile" is purely descriptive and does not necessarily imply the absence of any more specific underlying cause. It is disappointing that this analysis has indicated no means of distinguishing in life between these very different types of cases. This difficulty, however, serves as a warning against the diagnosis of myocardial ischemia in all cases of clinically obscure heart failure in the aged. Auricular fibrillation, which was common in all the etiological groups and also among the control subjects, did not appear to be related to coronary disease.

The Pathogenesis of Infarction of the Right Ventricle. W. G. Wade. Brit. Heart J. 21:545-554 (Oct.) 1959 [London].

It is rare for the right ventricle to be predominantly affected in myocardial infarction, the relative involvement of this ventricle in 2 large series being 1.7 and 3% respectively. In this paper there are presented the pathological and clinical features of 11 new cases of right ventricular infarction, the records of which were obtained from the Institute of Pathology of the University of Belfast. This constitutes the largest series of cases of this kind which has so far been published. Histological material was available in each case. For comparison, the corresponding gross pathological features in a consecutive series of 100 cases of left ventricular infarction investigated in this institute were also assembled.

The author concludes that extensive infarction of the right ventricle is usually a direct result of an occlusion of the right coronary artery. Earlier occlusive lesions occurring in the anterior descending branch of the left coronary artery probably play a considerable role in the pathogenesis of this type of infarct. Since the right coronary artery is usually the dominant vessel on the posterior cardiac wall, there is frequently an extension of the infarct to the posterior interventricular septum and adjoining portion of the left ventricle. It is

The place of publication of the periodical appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by persons in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1956 to date for English language and 1958 to date for foreign language journals. No photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

suggested that it is this extension of the lesion, rather than the involvement of the right ventricle itself, that contributes to the high incidence of circulatory failure in these cases. Extension of the infarct to the right atrium is also relatively common. There is evidence suggesting that pulmonary hypertension plays an etiological role in right ventricular infarction. When the thin-walled right ventricle becomes infarcted, the lesion is particularly liable to become transmural; hence, rupture, pericarditis, mural thrombosis, and pulmonary embolism are frequent attendant lesions.

The histological features of right ventricular infarction closely resemble those of left ventricular infarction. Without the assistance of an electrocardiogram including right precordial leads, there is little chance of achieving a precise clinical diagnosis. The prognosis in patients with right ventricular infarction tends to be poor, and the increased risk of pulmonary embolism makes the use of anticoagulant therapy imperative, although the tendency for hepatic insufficiency to develop necessitates great care in its use. Several physiological factors acting through the intercoronary collateral circulation are enumerated as being responsible for the relative immunity of the right ventricle to infarction.

Acute Benign Pericarditis and the Coxsackie Viruses. R. L. Gillett. New England J. Med. 261:838-843 (Oct. 22) 1959 [Boston].

The author presents clinical and laboratory data on 4 patients with the syndrome of acute benign pericarditis, who were among active-duty personnel stationed at the United States Naval Air Station, Jacksonville, Fla. Evidence of appreciable levels of antibody titers to the Coxsackie virus, group B, type 5, was demonstrated in the serum of the 4 patients. The stools were negative for the virus in 2 patients. One of these 4 patients was symptomatic for about 2 months, with persistence of a pericardial friction rub for about 10 weeks after the onset of symptoms. Another patient was symptomatic for about 10 weeks, and the pericardial friction rub was audible up to the 11th week of illness. Strict bed rest seemed to be an important factor in the treatment of these patients; salicylates proved helpful in relieving their symptoms and reducing fever. The indications for the use of salicylates should be similar to those in acute rheumatic fever.

Before it is suggested that a clinical syndrome represents a disease caused by a Coxsackie virus, the patient should be given an adequate clinical examination. The clinical syndrome should be one of previously undetermined etiology, not associated with, or related to, known pathogens. Antibody response to a virus of the Coxsackie group should be demonstrated coincident with the patient's illness. Virological and clinical evidence of poliomyelitis should be excluded. Least important, the Coxsackie virus should be recovered from the patient. Findings in the patients of this study give further evidence that the Coxsackie viruses may well be a major cause of the syndrome of acute benign pericarditis.

Anomalous Origin of the Left Coronary Artery from the Pulmonary Artery in an Adult. J. M. George and D. M. Knowlan. New England J. Med. 261:993-996 (Nov. 12) 1959 [Boston].

The 14th case of the anomalous origin of the left coronary artery from the pulmonary artery in an adult is reported; data on the 13 previously described cases are tabulated. In the 26-year-old woman whose history is presented, the anomaly was associated with rheumatic heart disease, a combination not previously described. Despite the presence of rheumatic heart disease with mitral insufficiency, cardiomegaly, and severe congestive heart failure, this patient survived to adult life with an anomalous origin of the left coronary artery from the pulmonary artery. The sudden death, which could have been attributed to many factors associated with rheumatic heart disease, is a common feature of an anomalous left coronary artery in adults. The vein-like appearance of the left coronary artery at autopsy suggests that the coronary supply of the myocardium in these patients is derived from the right coronary artery and that blood flow in the left coronary artery is toward the pulmonary artery instead of away from it.

Many surgical procedures have been suggested. Paul and Robbins advocated placing talc in the pericardium to increase blood flow to the myocardium. Others have recommended producing pulmonary hypertension and thus increasing perfusion pressure in the anomalous coronary artery. A transplantation of the portion of the pulmonary artery that contains the anomalous coronary artery to the aorta has also been suggested. Recently, Case and associates described a method of surgical correction, based on the fact that flow in the anomalous coronary is toward the pulmonary artery. They suggested ligation of the aberrant vessel at its origin; this converts the anomaly into a single coronary artery. They mentioned 3 infants who had been subjected to this procedure. As yet, no adult patients have undergone surgery.

Congenital Kinking of the Aortic Arch. J. N. Pattinson and R. G. Grainger. Brit. Heart J. 21:555-561 (Oct.) 1959 [London].

In the past few years a congenital anomaly of the aortic arch—a kinked or buckled arch—has been described and established as an entity. Although it usually presents a characteristic roentgenologic picture, it is not as yet widely recognized by either radiologists or clinicians. In this anomaly the descending portion of the aortic arch is acutely kinked, with an angular convexity directed forward, downward, and slightly to the right at the level of the ligamentum arteriosum. The kink occurs at the aortic isthmus, where there is normally a faint indentation on the concavity of the aortic arch immediately proximal to the slight dilatation (aortic spindle) of the upper descending aorta. The aorta proximal to the kink is elongated and rises higher in the mediastinum than usual. The ascending aorta is not dilated and is normally situated. The apex of the abnormal kink is closely applied to the upper and posterior aspect of the left pulmonary artery and left main bronchus, which may be displaced forward, downward, and to the right. The esophagus is also usually displaced forward and to the right, since it is closely applied to the kinked segment. The aorta immediately distal to the kink may be dilated. It turns sharply backward and slightly to the left, curving downward into a normally placed descending aorta.

The authors describe 5 new cases of kinked aortic arch without coarctation. The roentgenologic appearance of this anomaly is described in detail, not only from the posteroanterior but also from several other views. Thirty-seven cases of kinked aortic arch without coarctation have been previously reported or referred to. The abnormality is more frequent than this figure suggests; the authors have knowledge of, or have seen, several other patients not included in this series. The roentgenologic diagnosis is important, because otherwise the patient is frequently subjected to complicated, unnecessary, or uncomfortable procedures, such as angiography or even exploratory thoracotomy. The correct recognition is of practical importance to avoid the mistaken diagnosis of mediastinal tumor.

The Latex-Fixation Reaction in Nonrheumatic Diseases. E. Dresner and P. Trombly. New England J. Med. 261:981-988 (Nov. 12) 1959 [Boston].

The serum agglutinating factor for amboceptor-sensitized or FII (fraction II)-coated erythrocytes and latex particles is still thought to be specific for rheumatoid arthritis and closely allied diseases, and the variable occurrence of positive reactions in control subjects has not been satisfactorily explained. The incidence of these so-called false-positive reactions in serums from normal subjects and patients with nonrheumatic diseases varies in different reports from less than 1% to as high as 30%. This investigation represents a systematic attempt to delineate the conditions, other than rheumatic diseases, that regularly cause agglutination of FII-coated latex. Single and repeated samples of serum were obtained from 140 apparently normal subjects, 258 subjects with rheumatoid arthritis, connective-tissue diseases, and other rheumatic disorders, and 404 subjects with a variety of nonrheumatic diseases. Latex-fixation tests were performed on whole serums and on reconstituted euglobulin fractions by the inhibition-bloc technique of Ziff and collaborators, which was slightly modified. The merit of the inhibition-bloc technique as applied to sensitized erythrocyte and FII-coated latex systems lies in its great delicacy in detecting agglutinating activity in rheumatoid arthritis, but unfortunately this is not accompanied by a parallel increase in specificity of the reaction, even for the group of connective-tissue diseases as a whole.

The authors arrive at the conclusion that, when a sensitive inhibition-bloc technique is used, the latex-fixation test of Singer and Plotz is found not to be specific for rheumatoid arthritis. In addition to the connective-tissue group of diseases, positive reactions are consistently found in active hepatocellular diseases, the acute and convalescent phases of viral infections, seropositive syphilis, and some hyperglobulinemic states. The factor common to these conditions, and responsible for the latex fixation, is a circulating macrogamma globulin, which combines, probably in a nonspecific way, with the FII reactant coating the latex. The reaction is competitively inhibited by an excess of normal, low-molecular-weight gamma globulin. Latex fixation does not take place in the presence of abnormal gamma globulin of low molecular weight as in myelomatosis. Although they share some common physical properties, such as their molecular size, electrophoretic mobility, and ability to agglutinate FII-coated latex, pathological macroglobulins are probably not identical in other respects.

The Protean Manifestations of Histoplasmosis as Illustrated in Twenty-Three Cases. F. G. Conrad, S. Saslaw and R. J. Atwell. A. M. A. Arch. Int. Med. 104:692-709 (Nov.) 1959 [Chicago].

The authors report on 23 patients with histoplasmosis—6 from the Ohio Tuberculosis Hospital and 17 from the Ohio State University Hospital in Columbus—who presented diagnostic problems with a variety of manifestations. There were 13 men and 6 women, between the ages of 18 and 74 years, and 3 boys and 1 girl, between the ages of 3 and 11 years. Seven patients had acute disease resembling common respiratory infections. Of these, one died after dissemination of the disease, 2 required pulmonary resection, and in the others the condition cleared spontaneously with only symptomatic care. Ten patients had chronic, debilitating pulmonary disease resembling tuberculosis. Seven of them were treated for tuberculosis, and in 2 the presence of concomitant Mycobacterium tuberculosis was revealed by culture. Four of the patients with chronic histoplasmosis had exacerbations and remissions during the course of their illness. One patient had multiple arthralgias associated with weakness. He was thought to have sarcoidosis because of the granulomas which were seen in a liver biopsy specimen. This patient made a complete recovery on a regimen of modified rest alone. One patient presented as a typical case of hypersplenia; she had none of the usual symptoms of histoplasmosis and died of cerebral hemorrhage secondary to a thrombocytopenia. At autopsy, miliary involvement of spleen, lung, lymph nodes, and bone marrow was observed.

The treatment of histoplasmosis is mainly supportive. Surgery may be indicated for single localized lesions. Amphotericin B administered intravenously shows promise, but because of its side-reactions should be reserved for selected patients who show progression of the disease on symptomatic treatment and bed rest.

Late Progression of Pulmonary Coccidioidomycosis. M. J. Small. A. M. A. Arch. Int. Med. **104**:730-740 (Nov.) 1959 [Chicago].

The author reports on 4 men, between the ages of 25 and 52 years, with pulmonary coccidioidomycosis, who were admitted to the Veterans Administration Hospital in East Orange, N. J., in the past 2 years, and whose clinical course was strikingly different from that commonly accepted. In the first patient, the exposure to infection with Coccidioides immitis presumably occurred during Air Force service in Tucson, Ariz., in 1954 and early 1955, but was not clearly evident on a chest roentgenogram obtained at the time of discharge in February, 1955. In July, 1955, however, a coccidioidal cavity was present, and the clinical findings and those in the specimen of pulmonary segmental resection suggested that there was a bronchogenic seeding of the left lower lobe and pleura from this cavity and the subsequent surgical intervention respectively. In the second patient, there were a documented single exposure during Army service in Arizona, in an area endemic for coccidioidomycosis, in 1943; a negative chest roentgenogram obtained from the patient in 1946; a visible lesion on a chest roentgenogram obtained in 1951, slowly increasing in size by 1958; and clinical, skin test, and pathological findings in a lymph node biopsy, all of which pointed to a diagnosis of pulmonary coccidioidomycosis. In the third patient, a negative chest roentgenogram was obtained on induction into the Army in 1951, and a lesion appeared on a routine chest roentgenogram obtained in 1954 while the patient served in the Army in Arizona. This lesion remained stable for about 2 years but then showed evidence of a spread to the contralateral lung. The spread cleared while the patient was taking streptomycin and isoniazid, but a left apical lesion went into frank excavation and proved to be a coccidioidal cavity. In the fourth patient, a nodular lesion appeared in a chest roentgenogram obtained from the patient in 1945 when he was discharged after a 3-year Army service in western Texas. The appearance of this lesion did not change from 1945 to 1949, but there was a striking increase between 1949 and 1957, during which period the patient was not followed by chest roentgenograms. All smears and cultures proved to be negative for tubercle bacilli; tuberculin skin tests were negative; but the coccidioidin skin test was positive, and the resected specimen revealed a clean-walled cavity, the appearance of which was compatible with coccidioidomycosis.

These findings indicate that pulmonary coccidioidomycosis, contrary to the commonly held current concepts, may be a disease which does not manifest itself until a prolonged period after exposure in the endemic area, which may undergo late, continued, slow progression over a period of years, and which may spread by the bronchial route from cavities previously considered benign to produce infiltrations years later in the lung, indistinguishable by x-ray from those of exudative tuberculosis. Since these 4 cases were observed in persons residing in the East, whose x-ray manifestations of disease were not observed until from 5 months to many years after their documented residence in a known endemic area for coccidioidomycosis, it would appear that late pulmonary manifestations of coccidioidomycosis must be added to the list of differential diagnoses when considering stationary or progressive coin lesions, cavitary lesions without positive bacteriological findings for tuberculosis, and parenchymal infiltrations resembling tuberculosis, even years after exposure in an endemic area. Carefully taken histories eliciting residence in the endemic area, as well as the performance of the coccidioidin and tuberculin skin tests, have been the most helpful factors in leading to a positive diagnosis of late, active, pulmonary coccidioidomycosis in these patients. With the increasing tendency toward vacations by flight to the Southwest, it is felt that physicians in all areas of the United States must be alert to the possibility of this disease.

Disseminated Cryptococcosis Producing a Sarcoid Type Reaction: The Report of a Case Treated with Amphotericin B. L. H. Shields. A. M. A. Arch. Int. Med. **104**:763-770 (Nov.) 1959 [Chicago].

The author reports on a 42-year-old woman who had been working on a farm in North Carolina until she was admitted to the Harrisburg (Pa.) Polyclinic Hospital for incapacitating pain and swelling in the left shoulder, hip, and ankle, profuse sweating, frontal headaches, chills, fever, and loss of weight. The patient thus showed the picture of polyarthritis. The roentgenographic findings demonstrated that the disease was not limited to the joints, but was generalized. A clavicular biopsy showed cells suggestive of lipid granulomatosis, and a biopsy of a lymph node from the right axilla was consistent with sarcoid. The draining sinuses, lack of bacterial cause for the purulent exudate, septic course, multiple areas of involvement, and nonspecificity of pathological data suggested that a fungus was the causative agent. Appropriate studies resulted in positive cultures for cryptococci from a left supraclavicular abscess, from an osteolytic lesion in the external malleolus of the left fibula, the sternal marrow, and the spinal fluid. Mycotic organisms appearing as budding capsules, staining with mucicarmine, were identified. The diagnosis of cryptococcosis was indisputably established, although many of the aspects of the disease pattern suggested sarcoidosis.

Clinical remission was induced by slow infusion over 6 to 8 hours of amphotericin B; the patient received 2 courses with 54 therapeutic doses of the drug, totaling 3,162 mg., or about 45 mg. per kilogram of body weight. Dilution of the drug was effected to 1 mg. in 20 cc. of 5% dextrose in water. Laboratory evidence of drug toxicity of an acute nature was limited to a rise in blood urea nitrogen level after each infusion. The urea level was controlled when it reached 35 mg. per 100 cc. by omitting treatment for 1 or 2 days. Long-term laboratory toxic effects were difficult to separate from the effects of the patient's disease. There was a constant drop in hemoglobin level during both courses of therapy, not explained by bone marrow suppression or by hemolysis. The low white blood cell count with slight eosinophilia seemed to be related to the drug administration. There was a definite drop in serum potassium level during both courses of treatment.

Laparotomy 13 months after the institution of therapy showed involvement of the liver, spleen, and regional lymph nodes by a typical sarcoid-type reaction. Cryptococcic organisms were found in some of the granulomas. The clinical status of the patient in remission was indistinguishable from that seen in typical Boeck's sarcoidosis. It is believed that the widespread sarcoid-type reaction observed represents an immune response to primary cryptococcic invasion. The case of this patient is unusual in that the infective cryptococci have not only been associated with sarcoidosis, but have actually been observed in the area of sarcoid-type response, supporting the concept that the sarcoid reaction may be caused by various causative agents.

Porphyria Cutanea Tarda: Report of a Case Effectively Treated With Dimercaprol (BAL). A. G. Redeker, R. E. Sterling and B. Archer. A. M. A. Arch. Int. Med. 104:779-782 (Nov.) 1959 [Chicago].

The authors report on a 47-year-old man with "symptomatic" porphyria cutanea tarda, who was admitted to the Los Angeles County General Hospital in 1958. The skin of the patient's face, neck, and arms had an obvious dusky, violaceous hue, and he had mild hypertrichosis of the forehead. Numerous vesicles and reddish-black crusts were present on the face, neck, ears, arms, and hands. The ears were grossly edematous and oozed a clear fluid. There were a few shallow ulcers, a few large bullae, and many depigmented scars on the hands and forearms. There was no jaundice, and neither the spleen nor the liver could be palpated. The urine was of a burgundy color and contained large amounts of porphyrin. The patient's temperature on admission was 103 F (39.5 C). The patient was treated with bed rest, salicylates, and moist compresses applied to the ears. Two days later the temperature was restored to normal, and the patient appeared less toxic. But the urinary porphyrin excretion remained high, and new skin lesions continued to form. Dimercaprol was then administered in doses of 300 mg. per day for 4 days. Concurrent with the institution of this therapy, new skin lesions ceased to appear, and there was rapid healing of the preexisting ulcers and bullae. Two weeks after the patient's discharge from the hospital a few new bullous lesions had appeared on his hands, and the urinary porphyrin excretion had returned almost to pretreatment levels. Treatment with dimercaprol was then reinstituted, 150 mg. 2 times a week, and was continued for the following 3 months. During this period evidence of cutaneous photosensitivity was totally lacking, although very mild skin fragility persisted. The total porphyrin excretion was restored almost to normal.

The rapid clinical improvement resulting from dimercaprol therapy was accompanied by a decrease in both urine and fecal porphyrin excretion. Both abnormal sulfobromophthalein retention and a decreased serum protein level, present during relapse, became normal after dimercaprol therapy, emphasizing the role of hepatic dysfunction in patients with porphyria cutanea tarda. Treatment of this disease with dimercaprol is both safe and effective.

The Nephrotic Syndrome: Renal Biopsy Findings in Adults Responding to Prednisone. A. R. Sharpe Jr. and A. M. Unger. A. M. A. Arch. Int. Med. 104:684-691 (Nov.) 1959 [Chicago].

The authors report on 6 men and 2 women, between the ages of 24 and 41 years, with severe nephrotic syndrome, the clinical diagnosis of which was based on the presence of massive edema, heavy albuminuria ranging from 6.2 to 16 Gm. per day, and hypoalbuminemia ranging from 0.6 to 1.5 Gm. per 100 cc. The value of renal biopsy in the diagnosis and management of the nephrotic syndrome appears well established. Percutaneous renal biopsy, therefore, was performed on all the patients, and the outstanding pathological lesion in 6 of the 8 patients was thickening of the basement membrane. The biopsy findings were nearly normal in one patient. The absence of dilated, atrophic, or scarred tubules in all the patients was notable and of value in ruling out a chronic destructive process. No significant changes in the renal vessels were apparent, ruling out chronic renal-hypertensive disease.

When renal biopsy in adult patients with the nephrotic syndrome shows nearly normal glomeruli or generalized thickening of the basement membrane, it appears reasonable to institute a regimen of steroid therapy. These patients were treated intensively with prednisone at the Medical College of Virginia Hospital and the McGuire Veterans Administration Hospital in Richmond; 60 mg. of the drug per day in divided doses was given for the first 3 days of each week. Each month the dose was decreased by 5 mg. a day in order that at the end of one year the patient would have finished his treatment program. Diuresis to dryness was observed in every patient after the initial course of therapy. Proteinuria disappeared in only 2 patients. The remaining 6, while still excreting only small quantities of protein, were free of edema. Serum albumin concentration increased and serum cholesterol level decreased markedly after treatment. The blood urea nitrogen level remained essentially unchanged, except in one patient in whom there was a marked reduction. With the use of 60 mg. of prednisone per day, no serious complications occurred. "Moon face" appeared in 4 patients, and acne developed in 1. In none of the patients was it necessary to discontinue steroid therapy. Any conclusion as to the beneficial effects of this therapy must be drawn in the light of the natural history of the disease, as it is characterized by exacerbations and remissions. However, with the exception of one patient, all these patients had been continuously edematous for more than 3 months preceding the treatment, supporting the impression that the course of the disease was positively affected by steroid treatment.

Cardiovascular Disease Among Physicians. N. Reitman. J. M. Soc. New Jersey 56:673-676 (Nov.) 1959 [Trenton].

A questionnaire concerning the incidence of hypertension, obesity, stress and strain, diet, and diabetes in association with cardiovascular diseases was sent to 427 physicians in New Jersey. This sample group was selected at random, taking every 11th physician listed in the state. Two hundred sixty replies were received, 247 from male and 13 from female doctors. There were 25 cardiacs (10%) and 235 noncardiacs (90%). The cardiovascular diseases were rheumatic in 3 respondents, hypertensive in 7, arteriosclerotic in 13, aortic coarctation in 1, and thyrotoxic disease in 1. Hypertension was present in 28% of the 25 cardiac physicians, obesity in 10%, stress and strain in 92%, dietary restriction in 52%, and diabetes in 8%. In the noncardiac group the frequencies were: hypertension in 8%, obesity in 48%, stress and strain in 97%, dietary restriction in 34%, and diabetes in 1%. It appears that hypertension and diabetes are statistically significant factors in the incidence of cardiovascular disease in this sampling of New Jersey physicians.

Comparing the data obtained in this survey with the results of other studies on the subject, the author also concludes that mortality from heart disease among physicians in New Jersey is almost exactly the same as in the rest of the United States. There is a statistically significant increase in physician mortality from heart disease (66%) as compared with the incidence (53%) in the general population. New Jersey cardiac physicians are somewhat less obese and follow dietary restrictions more strictly than their noncardiac colleagues. Although stress and strain occur in a vast proportion of all physicians throughout the nation, no statistical evidence supports the popular concept that coronary artery disease is the doctor's disease. Coronary disease occurs more frequently among business executives of the same age group as physicians.

Chronic Granulocytic Leukemia. R. Menéndez Corrada. Bol. Asoc. méd. Puerto Rico 51:354-361 (Oct.) 1959 (In English) [Santurce].

Sixteen men in the early 40's, with chronic granulocytic leukemia, were hospitalized between 1950 and 1958 in the San Patricio Veterans Administration Hospital of San Juan. The diagnosis was made in most of the patients because of the presence of typical symptoms which had lasted for several months. It was also made in a few patients, in complete absence of symptoms, because of the accidental finding of a marked increase in the number of leukocytes and their precursors in the blood. All the patients but 4 had had anemia since the beginning of the disease. Although one of these 4 patients has lived longer than any other patient in the entire group (5½ years), it was found in the other 3 that the presence of anemia at the onset of the disease lacks any prognostic significance. The blood count in the patients on hospitalization was, on an average, 3 million erythrocytes and 170,000 leukocytes per cubic millimeter. The average age of the patients was 43 years. Three patients, who were treated between 1950 and 1953, received irradiation of the spleen as the only treatment, with no satisfactory results. Thirteen patients were treated with busulfan (Myleran), antibiotics, blood transfusion, and bone marrow inoculations between 1954 and 1958. Myleran was well tolerated, but resistance to it proved to be a warning of the occurrence of a blast crisis, which could be prevented by the administration of mercatopurine and large doses of steroids. Large doses of steroids seemed to prevent the crises and to prolong the patient's life.

Eight of the 16 patients died. Death occurred as the result of a blast transformation or crisis in 6 patients, of bronchopneumonia and anemia in one, and from rupture of the spleen in one. The average survival period after start of the treatment was 4 years. Eight patients, all treated with Myleran, are surviving at the present time, at periods which range from 1 to 5½ years since beginning of the treatment. Two patients are living in complete remission, not having had any treatment for 2 and 2½ years respectively. The alkaline phosphatase activity of the granulocytes reappeared during remission in these patients, and reached abnormally high levels which have been maintained up to the present time. Six patients had temporary remissions for periods which ranged from several months to one year; they were followed by relapses which again called for treatment. Myleran is the best available drug in the treatment of chronic granulocytic leukemia; it favors remissions and prolongs the life span of the patient.

The Electrocardiogram of Alcoholic Cardiomyopathy. W. Evans. Brit. Heart J. 21:445-456 (Oct.) 1959 [London].

When the ill-effects of alcohol on the myocardium are slight, withdrawal of alcohol can halt the pathological process, but should the earlier injurious effects go unheaded for some years, the resulting cardiomyopathy will not subside with abstinence from alcohol. It is for this reason that early myocardial damage from alcoholism is so important to detect. The author describes electrocardiographic changes that will facilitate the recognition of alcoholic cardiomyopathy. The first of the 20 patients studied by the author was referred to him by the family doctor on account of breathlessness and with a history of alcoholism over many years. This patient's electrocardiogram presented a change that had not been noticed hitherto in healthy adults or in patients with coronary arterial disease. The remaining 19 patients showed bizarre symptoms and signs associated with characteristic electrocardiographic changes and before a history of alcoholism was obtained. Abnormalities in the electrocardiogram were considered to be distinctive in 17, and although not so specific in the remaining 3, they suggested the diagnosis in these patients also.

The distinctive electrocardiographic deformities were limited to the T wave, which was a depressed dimple in 8 patients, upright and divided in 7, and spinous in 2. Whenever the T wave in chest leads was obviously inverted, as happened in 2 patients, the narrowness of the wave remained as a characteristic feature, and differed from the changes usually met in cardiac infarction. In 3 patients the presence of extrasystoles suggested the diagnosis, because they were multiple, arose from different foci, or were associated with moderate tachycardia. Extrasystoles were also present in company with the distinctive signs in 6 other patients. Auricular fibrillation was found in 2 patients, and paroxysmal auricular tachycardia in another 2. Bundle-branch block, present in 2 patients, and depression of the S-T segment, in 2, were regarded as sinister signs, for they occurred in the presence of enlargement of the heart with failure. Two patients exhibiting such cardiographic signs died. With these exceptions, abstinence from alcohol, together with digitalization in the 2 patients with fibrillation, sufficed to return the patients to health, and without the addition of thiamine therapy.

Administration of Fatty Acids and Arteriosclerosis: Use of the Intramuscular Route. R. L. Romero, N. N. D. de Feuillade and others. Semaña méd. 66:549-552 (Oct. 1) 1959 (In Spanish) [Buenos Aires].

Ten patients with arteriosclerosis were given a meal rich in saturated fatty acids, composed of 300 Gm. of potatoes, 100 Gm. of milk, 100 Gm. of butter, and 70 Gm. of bread. Five patients were given a capsule containing 250 mg. of linolic-linolenic ester after the meal. The remaining 5 received an intramuscular injection of the same unsaturated fatty acid mixture (800 mg. of Linacidin). Electrophoresis and determination of lipemia and cholesteremia were performed on all patients at 4-hour and 24-hour intervals. The results of these tests showed no appreciable changes in cholesteremia. The levels of lipemia, alpha and beta lipoproteins, and Antonini's beta-alpha quotient also decreased in all the patients, regardless of the form of administration of the fatty acids.

The authors conclude that the administration of linolic-linolenic ester is effective, both in preventing postprandial lipemia in patients with arteriosclerosis receiving a diet rich in saturated fatty acids and in lowering existing levels. The fact that no difference is observed between the effects of oral and intramuscular administration points to a lack of interference with the absorption of cholesterol. Apparently the unsaturated fatty acids do not influence the synthesis and resynthesis of cholesterol, and the cholesterol level apparently is not related directly to the sclerosing process. The apparent direct relationship is between arteriosclerosis and the alpha and beta lipoprotein levels. The authors believe that neither the changes in lipoprotein levels nor the absolute cholesterol values reflect the real problem in the etiology of arteriosclerosis. They may be atherogenic stimuli. The fundamental factor must lie in the chemical and textural alterations in the arterial wall as a result of continuous stress and spasm.

The Collection and Storage of Viable Human Fetal Hematopoietic Tissue for Intravenous Use. J. W. Ferrebee, H. L. Lochte Jr., H. Swanberg and E. D. Thomas. Blood 14:1173-1179 (Nov.) 1959 [New York].

The intravenous administration of cellular suspensions of homologous bone marrow induces recovery in a number of animal species after exposures to radiation which otherwise would prove lethal in a few days because of marrow failure. In some species, however, late deaths have been known to occur, and are apparently due to an immunological reaction of graft versus host or of host versus graft or perhaps to a failure to regain immunological responsiveness to endemic disease. Studies on immunological tolerance in fetal tissues suggested that the use of fetal hematopoietic tissue, rather than adult marrow, would diminish the incidence of these delayed deaths. Since evidence in mice has substantiated this point of view, the collecting and storing of human fetal hematopoietic tissues seems pertinent.

From the fact that the human fetus is relatively well differentiated by the end of the second trimester, it might be presumed that marrow obtained at term would have little immunological or hematopoietic advantage over adult cadaver marrow. Yet the authors have placed more emphasis on collecting hematopoietic tissue from the liver and spleen of fetuses of a gestation period of 12 to 20 weeks. The tissues were minced and then passed through a series of increasingly fine screens, of porosity 1,360, 630, 307, 201, 140, and 86 μ respectively. The screened minced tissue was resuspended and passed through a screen of 43 μ aperture. The final suspension contained approximately 0.4 billion liver parenchymal cells, 1.0 billion liver hematopoietic cells, and 0.03 billion splenic cells. This suspension was infused slowly over a 45-minute period without a clinical reaction. Postmortem examination of the recipient 9 days later failed to disclose embolic or other untoward results.

Minced and screened fetal liver and spleen were suspended in a series of dilutions of glycerol and human serum, type AB; 10 minutes at room temperature were allowed for equilibration, and then the several aliquots were cooled to —70C (—94 F) in dry ice. After a period of 6 weeks' storage at —70 C, the specimens were thawed, deglycerolized, and incubated with radiocarbon (C^{14}) formate or with tritiated thymidine. Studies of desoxyribose nucleic acid (DNA) synthesis rates with C^{14} formate and radioautograms after incubation with tritiated thymidine revealed that hematopoietic elements concentrated in these tissues at this stage of gestation maintain their viability during these periods of storage. Intravenous infusion of cellular suspensions prepared from stored frozen tissue, or from fresh tissue in this same age group, produced no observed untoward clinical reaction in the 3 patients studied. These preliminary observations demonstrate that hematopoietic tissue (liver and spleen) from fetuses in the 12-to-20-week gestation period has immunological, and possibly hematopoietic, advantages compared with adult or term fetal marrow. It may be able to acquire tolerance to its host, and it may have greater growth potential.

Staphylococcus Bacteremia: I. Clinical Review of 88 Cases from 1940 to 1958. V. Faber. Ugesk. laeger 121:1593-1601 (Oct. 15) 1959 (In Danish) [Copenhagen].

From 1940 to 1958, 48 men and 40 women with bacteremia due to Staphylococcus aureus were treated in Blegdam Hospital, Copenhagen; 51 cases were diagnosed up to 1957, and 37 cases in 1957-1958. There may be few symptoms at the start, or the onset may be explosive. Diagnosis can be made certain only by blood culture. Of the 34 patients with more or less grave complicating infection, 21 died; of the 54 without complicating infection, 20 died. The lungs were affected in 59 cases and the heart in 25 cases; there was cerebral or meningeal disease in 29 cases, osteomyelitis in 21 cases, and shock in 25 cases. For therapeutic success, early treatment with at least 2 antibiotics in high concentration is necessary, and this treatment should be continued for at least 4 to 6 weeks. Frequent blood culture with examination of the resistance pattern is necessary; it will also allow timely discovery of possible superinfection with other bacteria or fungi. Close supervision and control of cardiac, pulmonary, and renal function and possible complicating disorders are important. In manifest or threatening shock, steroid treatment is indicated.

Staphylococcus Bacteremia: II. Frequency, Origin, Portal of Entry and Mortality Studied in 201 Cases in 1957 and 1958. V. Faber, K. Rosendal and O. Jessen. Ugesk. laeger 121:1601-1607 (Oct. 15) 1959 (In Danish) [Copenhagen].

Staphylococcus aureus is the most frequently diagnosed cause of bacteremia. In 1957 and 1958 bacteremia was verified at the State Serum Institute and the Blegdam Hospital, Copenhagen, in 201 patients by cultivation of Staph. aureus from the blood. Of the 222 strains isolated, only 87 belonged to type 80 or the related type 52/52A/80. Application of antibiotics should be limited, since their use involves danger of change in the bacterial flora in the direction of resistant strains. Bacteremia was found in all age groups and was not restricted to patients with severe primary disease. At least half of the cases were characterized as hospital infections, and 50% of these were directly caused by surgical procedures and parenteral infusions. Otherwise, the most common portals of entry were boils and other cutaneous infections and pulmonary infections. The total mortality rate was 41%; the mortality was higher for infections acquired in hospital than for infections acquired elsewhere.

Staphylococcus Bacteremia: III. Some properties in Staphylococcus Aureus Isolated from Bacteremia Cases and Their Relation to Course of Infection. O. Jessen, V. Faber, K. Rosendal and E. R. Eriksen. Ugesk. laeger 121:1607-1614 (Oct. 15) 1959 (In Danish) [Copenhagen].

Two hundred twenty-two strains isolated from 201 patients with bacteremia due to Staphylococcus aureus were examined with respect to phage group, resistance to antibiotics, and formation of alpha lysin, hyaluronidase, and a lipase; in some cases they were compared with strains from impetigo, furunculosis, and normal nasal mucous membrane. Most of the bacteremia cases were due to strains of phage groups I and III. Most of the strains were penicillin-resistant; resistance to tetracycline occurred mainly in phage group III. Hospital strains were especially resistant. Bacteremia strains did not differ from strains of other manifest infections as to production of alpha lysin or hyaluronidase, and these 2 properties could not be correlated with the course of the infections. The mortality in bacteremia with antibiotic-resistant bacteria was 50 to 60% as against 17 to 40% in infections with sensitive strains. The prognosis was less favorable for bacteremia acquired in hospital than for infections which were not hospital-derived. The mortality was higher in bacteremia caused by lipase-negative strains than in corresponding infections with lipase-positive strains.

The Pathogenesis of Leptospiral Jaundice. F. Ramos-Morales, R. S. Díaz-Rivera, A. A. Cintrón-Rivera and others. Ann. Int. Med. 51:861-878 (Nov.) 1959 [Lancaster, Pa.].

There has been a great deal of speculation on the pathogenesis of jaundice in leptospirosis (Weil's disease). It has been attributed most frequently to hemolysis and intrahepatic biliary obstruction. The authors analyzed data obtained from the study of 235 patients with leptospirosis observed in Puerto Rico from 1948 to 1956. The diagnosis was confirmed by one of the following criteria: (1) isolation and identification of the Leptospira organisms from blood, urine, and/or spinal fluid; (2) serologic evidence of infection (complement fixation and/or agglutination-lysis tests) consistent with the clinical findings; and (3) postmortem evidence. Jaundice developed in 120 of the 235 patients. Since 50% of the patients were hospitalized before the 5th day of illness, the authors had ample opportunity to obtain dependable information on the appearance of jaundice. They found no evidence in support of hemolysis as a dominant factor in the genesis of icterus. No relation of cause and effect of anemia and jaundice was evident. Severe bilirubinemia appeared with unaltered red blood cell or hemoglobin values in the well-hydrated patients. Even among the anicteric, anemia may be attributed to blood loss, either internal or external, a negative nitrogen balance, high fever, azotemia (most prominent among the icteric, but rather common among the anicteric), parasitic infestations with chronic blood loss, and, in some instances, frequent phlebotomies for numerous laboratory examinations.

Laboratory evidence of hepatic dysfunction was recorded in both the anicteric and the icteric: abnormal cephalin flocculation, hyperbilirubinemia, urobilinogenuria, abnormal Bromsulphalein test, and impairment in synthesis of the serum proteins and cholesterol esters. The most intense hepatic dysfunction occurred during the second week of illness, as evidenced by the maximal increases in bilirubin and the alterations in cholesterol esterification. The authors emphasize that there were generally increases in the 1-minute and 30-minute fractions of serum bilirubin. A predominant 30-minute hyperbilirubinemia is occasionally observed early in the course of the disease and during convalescence. This phenomenon may be governed by either a decreased hepatic functional capacity or increasing loads of pigment derived from the reabsorption of tissue hemorrhages. It appears that the latter is of secondary importance in the pathogenesis of jaundice in leptospirosis. Transitory biliary tract obstruction, possibly intrahepatic, may be an aggravating factor in a minority of the jaundiced patients. The role of the impaired renal function in the maintenance of hyperbilirubinemia remains a subject for inquiry. Since there is no evidence to suggest that an increased catabolism of iron porphyrins (myoglobin) contributes to the development of jaundice, it is apparent that the most important factor in the pathogenesis of jaundice in leptospirosis is a decreased functional capacity of the liver.

A Critical Analysis of the Use of Salicylazosulfapyridine in Chronic Ulcerative Colitis. C. G. Moertel and J. A. Bargen. Ann. Int. Med. 51:879-889 (Nov.) 1959 [Lancaster, Pa.].

Reports on the use of salicylazosulfapyridine (also known as Azulfidine, Azopyrine, and Salazopyrine) in the treatment of chronic ulcerative colitis came from Stockholm in 1941. Bargen reported favorable results with it in the United States in 1948. The molecular structure of salicylazosulfapyridine is a combination of salicylic acid and sulfapyridine, these 2 substances being linked by a diazo bond. The studies described were made at the Mayo Clinic on patients with chronic ulcerative colitis, who were treated at the clinic for the first time between 1948 and 1952. The patients so treated were divided into 3 groups: (1) those treated with salicylazosulfapyridine (183 patients); (2) those treated with sulfonamides other [illegible] fapyridine (109 patients); and (3) those treated with general measures alone, or supplemented with antibiotics (131 patients). The aim was to compare the response to these different methods of treatment.

Salicylazosulfapyridine proved to be an effective agent in the control of the symptoms of chronic ulcerative colitis. When compared with treatment with other sulfonamide preparations and with general measures alone, treatment with this drug seemed to be superior in respect to both over-all symptomatic response and duration of hospitalization required to produce a favorable response. Undesirable side-effects occurred in about 1 of 6 patients treated, but these were minor and transitory. Serious hematological complications were rare, but blood counts should nevertheless be made periodically during therapy.

Although the initial response to long-term treatment with large doses of corticotropin (ACTH) or steroids would seem to be comparable to the response obtained with salicylazosulfapyridine, a comparison of length of hospitalization required, complications incurred, problem of withdrawal, and rate of recurrence or relapse seems to show that salicylazosulfapyridine has a very definite advantage. While this drug is not the final answer to the treatment of chronic ulcerative colitis, it has proved of considerable value in controlling the symptoms of the disease. Comparison with other commonly employed therapeutic methods indicated that at present it represents, when combined with the basic general and supportive measures, the treatment of choice of chronic ulcerative colitis.

Familial Hodgkin's Disease: Its Significance and Implications. D. V. Razis, H. D. Diamond and L. F. Craver. Ann. Int. Med. **51**:933-971 (Nov.) 1959 [Lancaster, Pa.].

The study group was composed of 1,102 patients with Hodgkin's disease, who had been seen at the Memorial Center for Cancer and Allied Diseases, New York, from 1918 to 1958. Many more patients with Hodgkin's disease have been seen at the center during these years, but either the histopathological diagnosis was unconfirmed or the case history could not be located. The objective of this epidemiologic study of familial Hodgkin's disease was to determine whether its familial concentration was significant or not. Four control groups were studied: a lymphosarcoma group (1,269 patients); a leukemia group (220); a malignant tumor group (748); and a group of patients with benign diseases (688).

From the data obtained, it appears that Hodgkin's disease occurs in families more often than one might expect from chance coincidence. Due to the great differences in the age distribution in this series, it is hard to be precise about the magnitude of the familial effect. The probability that the immediate relatives of a proband with Hodgkin's disease will also develop the disease is 3 times as great as the probability for the immediate relatives of a proband without the disease. Familial concentration in Hodgkin's disease, though statistically significant, is not very high. In this respect, the situation in Hodgkin's disease resembles most of the instances of reported familial human cancer. Hodgkin's disease apparently does not have a simple inheritance; heredity seems to play a relatively minor or indirect role in its etiology. Whether the familial concentration observed in this study is the consequence of heredity or of the greater environmental similarities for members within the family cannot be determined. The evidence, however, points more to environment than to heredity. Similarities in the time of onset of Hodgkin's disease (unrelated to age) in the affected relatives suggest the importance of "infectious agents." No statistically significant differences were found for familial leukemia and lymphosarcoma.

The Association of Multiple Arthritis with Carcinoma. M. S. Pathy. Rheumatism **15**:73-77 (Oct.) 1959 [London].

While the association of hypertrophic osteoarthropathy with chronic infection and malignant tumors, especially carcinoma of the lung, has become well recognized, it is not generally appreciated that polyarthralgia may be a symptom of carcinoma in various sites in the absence of hypertrophic osteoarthropathy. Two of the 4 patients, whose histories are described, presented with an acute multiple arthritis, and in the other 2 arthritis was a prominent feature of the disease. None of the patients had hypertrophic osteoarthropathy or clubbing of the fingers or toes. One of the patients had bronchial carcinoma, 2 had carcinoma of the stomach, and 1 had carcinoma of the pancreas. The cause of the arthritic manifestations is unknown. It is probable that the association of arthralgia with malignant tumors is more common than is generally appreciated. The possibility of a neoplasm should be considered when multiple joint pains with a raised erythrocyte sedimentation rate and pyrexia occur in a person over 40 years of age.

Evaluation of the Effect of Massive Prednisolone Therapy in Acute Leukemia. B. A. Bouroncle, C. A. Doan and B. K. Wiseman. Acta haemat. **22**:201-208 (Oct.) 1959 (In English) [Basel, Switzerland].

The authors report on 30 patients, 24 of whom had acute lymphatic leukemia, 5 had acute monocytic leukemia, and 1 had acute myeloblastic leukemia. There were 23 males and 7 females, 21 of them being between 18 months and 9 years of age, 4 between 14 and 18 years, and 5 between 19 and 40 years. All 30 patients had been treated with conventional therapy previous to treatment with massive doses of prednisolone; however, this conventional therapy had failed in inducing a remission. Prednisolone was then given orally in an average daily dose of from 500 to 1,000 mg. for 9 to 14 days. The average total dose per course of therapy was 9,300 mg. A complete remission, lasting from 3 to 11 months, was obtained in 7 of the 30 patients. Five of these patients had acute lymphatic leukemia, and 2 had acute monocytic leukemia. A partial remission was obtained in 3 additional patients who had been diagnosed as having acute lymphatic leukemia. No serious side-effects were evidenced in the patients treated in this series.

The results seem to indicate that massive corticosteroid therapy is of value in the treatment of selected patients having resistant acute leukemia. However, use of massive prednisolone therapy initially in the routine treatment of the acute leukemias before other available combinations of drugs have been tried is not recommended.

SURGERY

Surgical Treatment of Aortic Stenosis. R. J. Baird and W. G. Bigelow. Canad. M. A. J. 81:795-800 (Nov. 15) 1959 [Toronto].

The authors report on 65 patients with aortic stenosis, who were operated on at the Toronto General Hospital between November, 1953, and February, 1959. Transventricular dilatation was performed on 59 patients, 42 of whom were adults with pure aortic stenosis. Direct-vision repair with the aid of the heart-lung bypass machine was done in 6 patients who were older children or young adults. Special attention is paid to the group of 42 patients, 39 of whom were men, and the mean age was 43 years; 18 (42%) of the 42 had a positive history of rheumatic fever. The first symptoms were usually anginal pain, faintness or syncope, and dyspnea on exertion. The symptoms progressed rapidly in severity, and the rapidly downhill course after their onset made early operation imperative.

The 42 patients were divided into 4 groups on the basis of their symptoms: group 1 consisted of one patient who had no cardiac symptoms whatsoever; group 2 consisted of 15 patients with syncope and/or anginal pain and occasional mild dyspnea on exertion; group 3 consisted of 16 patients with left heart failure; and group 4 consisted of 10 patients with congestive failure. Seven of the 42 patients died in the hospital, i. e., an over-all mortality rate of 16.7%. The patient in group 1 survived, but 1 patient in group 2, 2 patients in group 3, and 4 in group 4 died; the mortality rate thus varied with the stage of the disease from zero to 40%. A follow-up of 6 months to 6 years revealed that 80% of the patients leaving the hospital are alive with moderate or marked improvement. In recent months the indications for repair under direct vision with the aid of the heart-lung bypass machine have been extended. In the lightly calcified valve of the younger adult, a more complete correction can probably be obtained by operation under direct vision with the aid of the heart-lung pump than by a blind dilatation. In the poor-risk or older patient, it is unlikely that it will supplant the blind transventricular procedure.

Primary Intracerebral Hemorrhage: Results of Surgical Treatment in 244 Consecutive Cases. W. McKissock, A. Richardson and L. Walsh. Lancet 2:683-686 (Oct. 31) 1959 [London].

Since neurosurgeons have become more interested in ruptured intracranial aneurysm, many more patients with acute cerebrovascular accidents have found their way to neurosurgical departments. Many patients admitted for "subarachnoid hemorrhage" have been shown to have cerebral hemorrhage, thrombosis, embolism, and other conditions. Of a total of 2,116 patients who had been admitted to a neurosurgical department because subarachnoid hemorrhage had been suspected, 1,183 had arterial aneurysms, 183 had angiomas, 278 had cerebral or cerebellar hemorrhages, and in 472 no lesions were detectable by angiocardiography. The authors report on 244 patients with primary intracerebral hemorrhage. These were partly derived from the 278 patients mentioned above. Excluded from this group were 28 patients with spontaneous intracerebellar hemorrhage (who are the subject of a separate report), also those with trauma, neoplasm, systemic disease, and primary pontine hemorrhage. There remained 179 cases of primary intracerebral hemorrhage presenting as subarachnoid hemorrhage. To these were added 65 cases in which the cerebrospinal fluid was clear or the findings at lumbar puncture doubtful. The diagnosis in all 244 cases was proved at operation or at postmortem examination.

The generally accepted picture of sudden onset with headache and vomiting, followed rapidly by the development of neurological signs and depression of consciousness, was present in less than half of the patients. In 201 of the 244 patients a lumbar puncture was performed; fresh blood was found in 161, no blood was revealed in 39, and in the remaining patient the result was dubious. In the 43 patients not subjected to lumbar puncture, the ventricular fluid was xanthochromic or blood-stained in 18. Thus, in 179 cases the cerebrospinal fluid indicated recent hemorrhage, in 48 it did not, and in 17 there was doubt. Twelve patients died before surgery could be undertaken, and 1 patient did not require an operation. The 231 patients underwent the following operations: ventricular tapping alone was done in 9; ventriculography, in 14; bur-hole exploration and evacuation of hematoma, in 104; bur-hole aspiration of hematoma with subsequent craniotomy, in 73; and craniotomy for evacuation of hematoma, in 31. There were initially 102 survivors among the 208 subjected to definitive surgery (bur-hole aspiration, craniotomy, or both). During the follow-up period, ranging from 1 to 10 years, 31 of the 102 patients died. The over-all mortality was 74%, and the surgical mortality 51%. Of the 63 survivors, 25 are well but 6 are totally disabled. The mortality is influenced by the following factors: (1) the site but not the size of the lesion (capsular hemorrhages carrying the worst prognosis); (2) hypertension, which is unfavorable; and (3) the state of consciousness, the death rate rising as the level of consciousness falls. The urgent use of ancillary methods of diagnosis (angiography and sometimes exploratory bur-holes) is emphasized.

Transthoracic Repair of Esophageal Hiatus Hernia: Evaluation of 200 Consecutive Cases. L. K. Groves, W. V. Martinez and D. B. Effler. J. Thoracic & Cardiovas. Surg. 38:537-552 (Oct.) 1959 [St. Louis].

In considering the advisability of surgical treatment for herniation of the stomach through the esophageal hiatus, it is important to know what risks are entailed, the probable effectiveness of the surgical treatment, and which patients should be advised to undergo surgery. The authors discuss these questions on the basis of observations on 200 consecutive patients who underwent transthoracic repair of esophageal hiatus hernias in the 6-year period from 1951 to 1956 inclusive. The effective repair of a hiatus hernia involves more than mere reduction of the hernia and "snugging-up" of the hiatus around the terminal esophagus. This form of repair involves a high incidence of recurrent herniation. Many factors, such as vomiting and straining in the postanesthetic period, may elevate the intra-abdominal pressure and force the stomach back up through even a very small hiatus. The placing of sutures from the margins of the hiatus into the friable esophageal musculature does not adequately protect against this hazard.

In the method of repair used by the authors, the free peritoneal cavity is entered by circumferentially incising into it immediately above the esophageal hiatus across the peritonized portion of the thoracic stomach. The upper end of the hernial sac, consisting of parietal peritoneum as well as phreno-esophageal ligament, then retracts to form a cuff that nicely defines the esophagogastric junction and holds sutures firmly. A ring of figure-of-eight sutures is placed deeply into this cuff and some of the underlying musculature. These sutures are brought down through the hiatus, and through stab wounds made with a ligature carrier, out to the superior surface of the diaphragm where they are tied to mattress sutures placed about the stab wounds to fix the esophagogastric junction below the hiatus. In the rare patient, in whom peptic esophagitis has resulted in scarring and fixed esophageal shortening to such an extent that the esophagogastric junction cannot be reduced below the esophageal hiatus, no treatment is completely satisfactory. It is the practice of these authors to raise the esophageal hiatus to the esophagogastric junction by incising upward from the normal hiatus toward the dome of the diaphragm, and to transplant the esophagus forward to this new and elevated position. In this fashion, considerable deficit in length can be overcome, particularly if the phrenic nerve is crushed to elevate the diaphragm maximally. It was necessary to transplant the esophageal hiatus in 20 of the 200 patients. In some of the patients who underwent the conventional repair and in a few who required transplantation on account of a short esophagus, a myotomy was performed in the terminal esophagus.

The results in 180 of the 200 patients who could be followed for from 6 months to 6½ years are tabulated. The results were excellent in 97, good in 52, fair in 15, and the treatment failed in 16 patients. The authors believe that operation is mandatory in a small proportion of patients who have complications, including bleeding, peptic ulceration, stricture of the terminal esophagus, or mechanical obstruction. In the large majority of patients, the operation is elective. These patients will obtain excellent operative results if they are carefully selected for surgery. In retrospect, the largest number of preventable operative failures have been classified as being due to a poor choice of operative candidates, including chiefly emotionally unstable patients and those whose gastrointestinal problems are largely functional.

The Surgical Relief of Chronic Myocardial Ischemia. R. Kauntze, D. McGill and R. Brock. Lancet 2:631-634 (Oct. 24) 1959 [London].

The authors report on 10 men, between the ages of 42 and 62 years, with progressive and incapacitating anginal pain due to overwhelming myocardial ischemia, in the absence of cardiac enlargement, cardiac failure, severe hypertension, and generalized arterial disease. The patients underwent a simple procedure of abrading the parietal and visceral pericardium in an attempt to produce a myocardial reaction sufficiently brisk to improve the intercoronary anastomoses. In all the patients the anginal pain was uncontrolled by treatment preceding the surgical intervention. Of the 10 patients, 9 survived the operation. One of the survivors is outstanding in that he works full time and is quite free from anginal pain with ordinary activity; 10 minutes' exercise failed to produce pain 6 months after the operation. The condition of 2 other patients has improved strikingly, while the results may be classed as good in 5 additional patients. Improvement was slight or absent in only one patient. Serial electrocardiograms were of little value in the assessment of myocardial blood supply after the operation, and the assessment of these patients was mainly on clinical evidence. Improvement in pain and dyspnea on effort has been most 4 months after operation, when the psychological effects of special investigation and operation and follow-up would be expected to be waning, if not already absent. Fatigue was a particular complaint in early convalescence, although right ventricular failure occurred in the immediate postoperative period in only one patient; it cleared up within 3 weeks.

Diagnosis of Thyroid Cancer: Forty Cases of Infiltrating Carcinoma. O. F. Grosso, P. Paseyro and J. Maggiolo. An. Fac. med Montevideo 44:53-80 (Jan.-April) 1959 (In Spanish) [Montevideo, Uruguay].

Forty patients with infiltrating carcinoma of the thyroid were observed in the Instituto de Endocrinologia of the Faculty of Medicine of the University of Montevideo. Thirty-four of the patients were female, and 6 were male; they were observed for the first time at an age which ranged between 11 and 75 years. Carcinoma of the differentiated type was found in 35 patients, and of the undifferentiated type in 5. The group of patients with differentiated carcinoma included 20 with papillary carcinoma and 12 with follicular adenocarcinoma; one patient had a Hürthle-cell tumor, and two had a solid thyroid tumor. The greatest incidence of differentiated carcinoma was in patients between 41 and 50 years of age; undifferentiated carcinoma occurred mostly in patients between 55 and 65 years of age.

Diagnosis of differentiated thyroid carcinoma is difficult. The following clues are suggestive: (1) presence of a nodular goiter, especially in children and in young adults; (2) a thyroid tumor of rapid growth; (3) simultaneous or successive appearance of a thyroid tumor and of cervical lymph node enlargement; (4) recurrence of a thyroid tumor after resection; and (5) signs, symptoms, or presence of visceral, bone, or lymph node metastases of unknown origin. Puncture cytology is of value in deciding the diagnosis of undifferentiated thyroid carcinoma.

Lobectomy for Bronchial Carcinoma. J. R. Belcher. Lancet 2:639-642 (Oct. 24) 1959 [London].

The author reports on 264 patients with bronchial carcinoma, who underwent lobectomy and were followed up for 5 years or more. Of the 264 patients, 12 died as a direct result of the operation, and an additional 6 were lost to follow-up. Of the remaining 246 patients, 141 died less than 5 years after the operation, 14 died between 5 and 10 years after the operation, and 91 (37%) were alive at 5 years. Thirty (12%) of the 246 patients died of causes other than bronchial carcinoma, and, if these are excluded, the 5-year survival rate is 42%. The 5-year survival rate among patients with adenocarcinoma was 53%; among those with oat-cell carcinoma, 37%; and among those with squamous carcinoma, 32%. This difference was not due to the different incidence of invasion of lymph nodes. The 5-year survival rate among patients with involvement of lymph nodes was 23%, as compared with 43% among those in whom the lymph nodes were tumor-free. The survival rate was significantly better among patients with lower-lobe tumors (44%) than among those with upper-lobe tumors (31%). Carcinoma developed in the residual lung of 19 patients (7.5%); in 11 patients it was thought possible that these might be new primary tumors.

If lobectomy, as compared with pneumonectomy, were an inadequate operation, the tendency toward conservatism in the surgical treatment of bronchial carcinoma would have been reflected in a lower over-all survival rate. This has not been shown. It seems, therefore, that on both pathological and statistical grounds the present popularity of the more conservative resection in the treatment of bronchial carcinoma is justified.

Ventricular Aneurysm Following Myocardial Infarction: Results of Surgical Treatment. D. A. Cooley, W. S. Henly, K. H. Amad and D. W. Chapman. Ann. Surg. 150:595-612 (Oct.) 1959 [Philadelphia].

Ventricular aneurysm is a frequent late complication of extensive myocardial infarction. Although cardiac rupture is rare, serious and frequently incapacitating symptoms result from the impairment of cardiac function produced by the noncontractile, expansile aneurysm. Embolism from mural thrombi may also produce serious complications. The authors present observations on 6 patients in whom aneurysm of the left ventricle resulted from myocardial infarction. In all of them excision of the ventricular aneurysm was performed with the aid of a pump oxygenator for temporary cardiopulmonary bypass. A stainless steel oxygenator based upon the bubble diffusion principle was used. DeBakey roller pumps of the complete occlusion type were used to withdraw venous blood from the venae cavae and to return oxygenated blood to the systemic arterial system. Cardiac catheterization studies were performed prior to surgery in 5 of the 6 patients. They revealed a reduction in cardiac output and significant pulmonary hypertension. After operation cardiac function improved, and all patients obtained clinical benefit. The pathological state of the diseased myocardium determines the optimum time for the surgical intervention after myocardial infarction.

Another complication of severe myocardial infarction, which the authors treated by open cardiac techniques, was acute perforation of the interventricular septum. The histories of 2 patients with this complication are briefly described, because they support the opinion that after infarction a delay of at least 6 weeks, and preferably 3 months, is necessary for satisfactory ventricular recovery. Surgical excision and ventricular repair are a feasible and rational surgical treatment for ventricular aneurysm after myocardial infarction when the lesion is of sufficient size to cause impairment of cardiac function.

Continuous Endobronchial-Pulmonary Medication: Preliminary Note. L. Bonelli, L. Baglione, D. Rochat and G. Bologna. Minerva med. 50:3275-3290 (Oct. 17) 1959 (In Italian) [Turin, Italy].

Continuous endobronchial-pulmonary treatment with perfusion, with drugs introduced through a plastic tube into the respiratory system by the cricothyroid route, was given to 97 patients. Good results were obtained in 8 patients with bronchiectasis, in the sense that peribronchial disorder disappeared and discharge was reduced or eliminated. Of 4 patients with pulmonary abscess, complete remission was obtained in 1 patient who had the acute phase of the disease, and good or very good results in 3 patients who had the chronic variety of the disease. Eighty-five patients with chronic tuberculous cavities, who had been hospitalized for more than a year, received the treatment for the purpose of ameliorating severe localized conditions. Improvement was obtained in 52 patients, but there was no change in 28 patients, and deterioration in 5. The patients tolerated the insertion of the plastic tube well, and almost all became accustomed to carrying it after a few days. A subcutaneous cervicofacial emphysema developed in 2 patients, who had avoided bed rest during the first day of treatment; the condition was resolved in 2 days. The tube, which broke internally in 4 patients, was removed by bronchoscopy; the break was probably related to faulty material. The authors conclude that the experience with this procedure warrants its further application. They suggest inserting the tube in some of the patients 30 days before and resuming its insertion after the pulmonary resection.

Pericarditis Following Pneumonectomy for Pulmonary Tuberculosis. P. De Roover and A. Lacquet. Brit. J. Dis. Chest 53:356-359 (Oct.) 1959 [London].

A case of exudative pericarditis occurring after pneumonectomy for pulmonary tuberculosis is reported. The patient, a 46-year-old man, had had pulmonary tuberculosis for over a year. His right upper lobe was shrunken and contained many cavities. The patient was admitted to the tuberculosis department of the University Clinics in Louvain, Belgium, where he was treated with tuberculostatic agents and complete rest. After a 7-month treatment the sputum became negative, and a pneumonectomy was performed, with removal of part of the pleura. The lower lobe could be freed without opening the pericardium. The immediate postoperative course was fairly good. On the 16th postoperative day the patient suddenly developed fever and became dyspneic; ascites and edema developed progressively in the lower limbs; the blood pressure dropped, and the circulation rate became markedly slow. A roentgenogram showed hydropneumothorax on the right side, while the only abnormal electrocardiographic finding was a flattened T wave. A few days later, as the roentgenologic examination revealed a markedly enlarged heart shadow, a puncture of the pericardium was performed, with drainage of 400 cc. of a seropurulent fluid. The patient improved immediately, and the blood pressure rose from 55/45 to 110/70. The puncture was repeated later, but the patient declined rapidly and died one month after the operation.

The authors call attention to the danger of an unnoticed exudative pericarditis which may be concealed behind the diagnosis of "cardiac decompensation." Before establishing such a diagnosis, the possibility of an exudative pericarditis should be investigated. Pericarditis should be suspected whenever the patient has a prolonged period of fever after the operation. The prognosis is poor, although pericardial punctures may bring about a complete cure.

The Operative Risk in Cardiopathic Women. G. Atlante and G. Giorgetti. Policlinico (sez. chir.) 66:350-374 (Oct.) 1959 (In Italian) [Rome].

The authors report a study on a series of 419 cardiopathic women, 24 to 79 years of age, operated on for gynecologic diseases at the gynecology and obstetrics clinic of the University of Rome from January, 1953, to December, 1957. One hundred seven patients were suffering from mitral insufficiency, 23 from mitral insufficiency and stenosis, 19 from aortic lesion, and 6 from mitral and aortic lesions. One hundred eighty-seven patients were operated on for fibromatosis of the uterus, 51 for cancer of the endometrium, and 40 for cancer of the neck of the uterus. Laparotomy was performed on 345 patients (82.3%), vaginotomy on 70, vesicotomy on 2, and mastectomy on 2. Good results were obtained in most instances. Among the survivors were 6 patients with atrial fibrillation, 2 of whom underwent total hysterectomy; 1, subtotal hysterectomy; 1, vaginal hysterectomy with plastic;

1, myomectomy; and 1, explorative laparotomy. Each of these patients received digitalis during and after the operation; anesthesia was induced with thiopental (Pentothal) and a mixture of nitrogen peroxide and oxygen. Results were also good in 207 patients whose electrocardiograms showed signs of damage to, alterations or lesions of the myocardium, and an abnormal rhythm. Only 3 postoperative incidents of paroxysmal tachycardia were recorded.

Anesthesia was induced by means of Pentothal, tubocurarine or succinylcholine, nitrogen peroxide and oxygen in 388 instances; by Pentothal and oxygen in 12; by ether and Pentothal in 4; by ether, nitrogen peroxide, and Pentothal in 5; by ether only in 7; and by spinal anesthesia in 1. Nitrogen peroxide was administered as a local anesthetic to 2 patients. Cardiovascular disturbance followed the operation in 16.8% of the cases. Ten of the 419 patients died. In 3 patients, however, death was the result of causes not related to the cardiopathy; 2 of these patients died of neoplastic cachexia and liver insufficiency due to metastases of carcinoma of the ovary, and 1 of severe septicemia. None of the patients died during the operation, and one died the first day after the operation.

The authors believe that, though the operative risk has been greatly reduced in cardiopathic patients, it is still useful to consider each case individually and to adopt an attitude of "preventive diffidence." On the basis of this the most suitable preoperative therapy and the least traumatic operation, as well as the most suitable anesthetic and postoperative treatment, will be chosen.

Spontaneous Idiopathic Segmental Infarction of the Omentum. H. N. Blansfield and P. C. Jameson. Connecticut Med. 23:697-699 (Nov.) 1959 [New Haven].

The authors report 2 patients with spontaneous idiopathic segmental infarction of the omentum. The first patient, a 6-year-old girl, was admitted to Danbury (Conn.) Hospital with severe abdominal pain of 2 days' duration, localized in the right lower quadrant, accompanied by anorexia and vomiting. Her history revealed a mild infection of the upper respiratory tract, associated with coughing, one week before admission. There was no history of constipation, of diarrhea, or of trauma. Physical examination was unremarkable except for tenderness in the right lower quadrant of the abdomen, with spasm and rebound tenderness. A diagnosis of acute appendicitis was made. At laparotomy a serosanguineous fluid was encountered in the abdominal cavity. The appendix was normal, but a firm rubbery mass of omentum covered with fibrinous exudate was found in the right upper quadrant. This lesion was resected, and appendectomy was performed. Pathological examination of the surgical specimen revealed congestion, hemorrhage, and perivascular infiltration with polymorphonuclear leukocytes. The vessels were thrombosed. The pathological diagnosis of omental infarction was made. The patient's postoperative course was uneventful.

The second patient, a 72-year-old woman, was admitted to Danbury Hospital because of pain in the right lower quadrant of the abdomen for the last 5 days, which was aggravated by walking and standing. She had no nausea and no vomiting. The patient's history revealed that 3 weeks before admission she had had a mild infection of the upper respiratory tract, associated with laryngitis, bronchitis, and mild coughing, and that 12 years before she was subjected to hysterectomy and appendectomy. Roentgenograms of the gastrointestinal tract were normal. Physical examination of the abdomen revealed a palpable lemon-sized tender mass in the right iliac fossa. There was no rebound tenderness and no rigidity, but voluntary spasm was present on deep palpation in the right lower quadrant. A diagnosis of a retroperitoneal tumor was made, with the possibility of a lymphosarcoma. At laparotomy a lemon-sized infarcted mass of omentum was found adherent to the anterior cecal wall. The infarcted tissue occupied the right free border of the omentum. The intestine revealed no intrinsic disease, such as tumor, ulceration, or diverticulitis. There was no torsion of the omentum, and no adhesions surrounded it. The infarcted omental mass was resected. The pathological diagnosis of omental infarction due to unknown cause was made. The patient's postoperative course was uneventful.

It is of interest to note that both patients had had infection of the upper respiratory tract before onset of the abdominal symptoms. This corresponds with Totten's theory that increased abdominal tension, coincident with coughing and sneezing, might be sufficient to cause rupture of the omental veins, leading to hemorrhage and secondary thrombosis. Omental infarction is a significant cause of error in the diagnosis of abdominal disease. This lesion should be considered in patients manifesting vague, atypical abdominal symptoms, in both acute and chronic conditions.

Frequency of Staphylococci Resistant to Penicillin and Streptomycin in Infections in Surgical Out-Patients. K. R. Eriksen and N. Dons. Ugesk. laeger 121:1553-1556 (Oct. 8) 1959 (In Danish) [Copenhagen].

Staphylococcus aureus was isolated from 1,136 outpatients with abscesses, boils, paronychia, and other subcutaneous infections. From 1949 to 1958 the frequency of penicillin-resistant staphylococci rose from 10 to 57.6% and the frequency of streptomycin-resistant staphylococci, from 0 to 35.5%. In the 814 patients who had not had contact with hospitals and had not been treated with antibiotics, the frequency of penicillin-resistant staphylococci rose from 4.5 to 46.1% and the frequency of streptomycin-resistant staphylococci, from 0 to 22.6%.

Hypoglycemia Due to Nonpancreatic Mesodermal Tumors: Report of Two Cases. D. R. Miller, R. E. Bolinger, D. Janigan and others. Ann. Surg. **150:** 684-696 (Oct.) 1959 [Philadelphia].

Although Whipple's triad, consisting of "attacks of nervous or gastrointestinal disturbances in the fasting state, associated with hypoglycemia and immediate relief of symptoms after the ingestion of glucose," may be produced by intrinsic liver disease, adrenal insufficiency, or pituitary disturbances, the surgeon's primary interest in the triad has been its association with functioning islet-cell tumors of the pancreas. There have also been reports on nonpancreatic tumors associated with Whipple's triad. The authors were able to trace literature reports on 15 such patients, and they present the histories of 2 additional patients who were studied at the University of Kansas Medical Center, Kansas City. One patient was a 73-year-old man, and the other a 59-year-old woman. The clinical features observed in these 2 patients were like those found in 15 previously reported patients.

Distal pancreatectomy did not abolish the hypoglycemia in either of these patients. In the first patient, removal of a large pelvic tumor was not possible, and he died as the result of complications of the large pelvic sarcomatous mesodermal tumor involving the prostatic area. The second patient completely recovered after removal of a large diaphragmatic fibrous mesothelioma. Assays for insulin activity were done upon tumor tissue from both patients. Postmortem autolysis probably prevented finding insulin activity in the tumor of the first patient. In the second patient, insulin activity was demonstrated, lending support to the theory that an insulin-like substance is produced by the tumor. The characteristics of the tumors and theories of hypoglycemia etiology are discussed.

The Physiological Response of the Small Bowel of the Dog to Ischemia Including Prolonged in Vitro Preservation of the Bowel with Successful Replacement and Survival. R. C. Lillehei, B. Goott and F. A. Miller. Ann. Surg. 150:543-560 (Oct.) 1959 [Philadelphia].

New surgical techniques and ideas for treating conditions involving the intestine and/or its vasculature have been slow to evolve, because of misgivings that anastomoses involving these vessels will not remain open. There is insufficient knowledge about the ability of the small intestine to survive complete or partial occlusion of its vasculature while conditions affecting the superior mesenteric vessels are dealt with. Finally, nothing is known about the fate of the small intestine after severance of its connections with the central nervous system and after division of its lymphatic drainage. In studies on the effect of ischemia on the small intestine of dogs, the authors made serial determinations of the plasma volume, hematocrit, and plasma hemoglobin before, during, and after experiments, as well as gross and microscopic observations on the intestine itself.

It was found that the majority of adult mongrel dogs tolerated up to 3.5 hours of superior mesenteric arterial occlusion if the collateral circulation to the small intestine was not disturbed. If all collateral circulation to the intestine was occluded as well, then most dogs died after a 3-to-3.5-hour occlusion of the superior mesenteric artery. Interruption of all circulation to the small intestine for 2 hours was tolerated if the intestine was allowed to cool to room temperature, 25 to 28 C (77 to 82.2 F). If, however, the intestine was cooled to 5 C (41 F), then it was safe to interrupt all circulation to the small intestine for at least 5 hours.

Knowing this, the authors removed the entire small intestine, save for the first few centimeters of duodenum, and held it in vitro. No external cooling of the intestine was required if it was returned to the peritoneal cavity and circulation reestablished within 2 hours. If cooled to 5 C (41 F) in vitro, it was not necessary to reestablish circulation for up to 5 hours. In every case the intestine retained its viability, and many of the dogs survived for weeks or months, indicating that the intestine could survive complete severance of all connections with the central nervous and lymphatic systems and that anastomoses of the superior mesenteric vessels, especially those of the veins, would remain open. This technique was also used to make small intestine homografts in dogs, which have so far lasted up to 7 days.

Hodgkin's Disease of the Cecum: Report of a Case. W. A. D. Alonzo. J. Internat. Coll. Surgeons 32:479-490 (Nov.) 1959 [Chicago].

The author reports a case of Hodgkin's disease in a 23-year-old man in whom the disease was first manifested in the cecum and clinically resembled appendicitis. On admission to St. Joseph's Hospital in Philadelphia, the patient had severe continuous pain in the right lower abdominal quadrant, with no radiation. He felt nauseated after having eaten breakfast. Marked tenderness and some muscle guarding were elicited over McBurney's point. Rectal examination elicited a great deal of tenderness in the right side of the pelvis, but no masses were detected by palpation. The temperature was 99 F (37.2 C). The hemoglobin level was 12.3 Gm. per 100 cc., the erythrocyte count was 4 million per cubic millimeter, and the leukocyte count was 10,300 per cubic millimeter. A diagnosis of appendicitis was made, and the patient was operated on. The appendix was normal, but the cecum contained a hard, firmly fixed mass, posteriorly situated and about the size of an orange, which was thought to be a carcinoma. The serosa was edematous and injected. The incision was closed in layers, and the patient was prepared for right-sided colectomy with succinylsulfathiazole (Sulfasuxidine), given for 3 days, and neomycin, given for 24 hours. On reoperation, normal conditions were observed throughout, except for the hard fixed mass in the head of the cecum. Just below and medial to the cecal mass were 2 firm and discrete lymph nodes, each about the size of an almond. The terminal portion of the ileum, cecum, and ascending colon to the midtransverse portion were resected, and an end-to-side ileotransverse colostomy was performed. Gross and microscopic examination of the operative specimen revealed Hodgkin's disease, involving the cecum and 2 out of 7 regional lymph nodes. The resected margins were free of disease. The patient was carefully studied for systemic evidence of the disease, with negative results. He made a good recovery from the operation, returned to work as an automobile mechanic, and offers no complaints.

Hodgkin's disease may occur in the gastrointestinal tract, though its primary occurrence in the cecum is rare and may be confused grossly at the operating table with carcinoma. The author reviewed the literature on Hodgkin's disease of the gastrointestinal tract in general, with special emphasis on the cecum. Hodgkin's disease of the cecum occurs chiefly in the third decade of life. Its incidence is the same in men as in women. The clinical picture is characterized by dull, constant pain in the right lower quadrant of the abdomen, associated with anorexia, nausea, and slight loss of weight. Neither hematemesis nor melena was usual or frequent in the cases collected from the literature. Some of the workers advocated surgical resection combined with roentgenotherapy for localized Hodgkin's disease of the gastrointestinal tract. When the lesions are inoperable or surgical intervention is contraindicated, roentgenotherapy is advocated for the amelioration of symptoms and the prolongation of life. The opinion has been expressed that in cases of Hodgkin's disease localized to the cecum, in which resection has been done, roentgenotherapy should not be used.

Hydrocortisone in Surgical Stress. E. M. Greisheimer. J. Am. M. Women's A. 14:897-899 (Oct.) 1959 [Baltimore].

The author mentions 3 important groups of hormones that are elaborated by the adrenal cortex. She is concerned with hydrocortisone, the chief constituent of the corticoid group of hormones, which during and after periods of stress, such as in connection with surgical operations, may be found in increased quantities in the peripheral blood. If one is to treat chronic adrenal insufficiency or acute adrenal insufficiency arising during or immediately after surgery, one should know the amount of hydrocortisone produced by the adrenal glands in normal individuals. It has been estimated by radioactive methods that the human adrenal glands supply about 30 mg. of hydrocortisone or similar steroid daily. A person who has undergone total adrenalectomy needs about 1 mg. of hydrocortisone, given by intravenous infusion hourly, to remain free of symptoms of adrenal insufficiency.

After satisfactory methods of determining hydrocortisone levels in the plasma became available, a test of adrenocortical capacity was devised, based on changes in plasma levels of hydrocortisone during and after administration of corticotropin (ACTH). Fifteen to 25 I. U. of ACTH in saline or dextrose solution are given intravenously over a period of 4 to 6 hours. The level in plasma rises markedly in the presence of normal adrenal glands and returns to the initial level about 6 hours after the cessation of infusion. The response is decreased in Addison's disease, entirely lacking in the absence of adrenocortical tissue, and exaggerated in patients with adrenal cortical hyperfunction (Cushing's syndrome) and in normal women during the third trimester of pregnancy. There is increased activity of the adrenal cortex, probably due to emotional stress, during the preoperative period. Since it is possible to evaluate the capacity of a patient's adrenal cortex before surgery and, in view of the information about the daily amount of hydrocortisone produced, it is advisable to administer this hormone in adequate doses to patients whose adrenal glands are unable to respond normally to the stress of surgery. Hydrocortisone therapy offers a means of protecting patients from postoperative shock. Serious postoperative complications may ensue if the adrenal glands are hypoactive and hydrocortisone therapy is neglected. Histories of surgical patients should always include information regarding previous use of cortisone, hydrocortisone, or ACTH therapy, because if a patient has been taking cortisone or hydrocortisone, surgery may produce an adrenal crisis.

Changes in Number of Thrombocytes Under the Influence of Brain Surgery. W. Umbach, E. Grözinger and K. Hummel. Klin. Wchnschr. 37:1069-1073 (Oct. 15) 1959 (In German) [Berlin].

Every surgical trauma causes changes in the blood distribution and in this way brings about alterations in the thrombocyte count in the circulating blood. In interventions on the central nervous system, the centers that regulate the composition of blood are influenced, and thus there occur, in addition to the "traumatically" elicited thrombocyte fluctuations (loss by hemorrhage or by the formation of coagulation thrombi), changes in the regulatory mechanisms for thrombocytopoiesis and thrombokinesis. Continuing earlier studies, the authors investigated the number of thrombocytes, before, during, and after surgical interventions, in the brains of 53 patients. The operations included 18 on the cerebrum and 8 on the cerebellum; there were 7 ventriculographies (which in 6 cases were immediately followed by cerebellar interventions), 4 stereotactic exclusions in the regions of the subcortical nuclei for parkinsonism, and 9 spinal operations; the others included exclusions of the hypophysis with radiogold (Au^{198}) or irradiations of localized tumors by radio cobalt (Co^{60}).

In the course of most of these operations, the number of thrombocytes decreased during and in the first 24 hours after the operation. This initial decrease results from the surgical blood loss, but particularly from the physiological "consumption" of the thrombocytes during hemostasis. Very great, and sometimes prolonged, fluctuations in the number of thrombocytes occurred during interventions on the hypophysis, in the course of ventriculographies, in the presence of hydrocephalus, and in deep-lying processes close to the diencephalon. Increases in thrombocytes predominated; the initial thrombocyte count was often exceeded, and this increase frequently persisted for a relatively long period. This is probably caused by an irritation of the hematopoietic centers in the diencephalic regions, which alter the emergence of the thrombocytes from the bone marrow and their distribution in the blood stream. There is a parallelism between these changes in the thrombopoietic system and the known changes in the leukopoietic and erythropoietic systems after central nervous system irritations. These findings complement earlier information about the central regulation of the hematopoiesis.

Physiologic and Surgical Problems in the Management of Primary Aldosteronism. B. Zimmermann, W. H. Moran Jr., J. C. Rosenberg and others. Ann. Surg. 150:653-665 (Oct.) 1959 [Philadelphia].

Patients with primary aldosteronism present themselves usually with a history of hypertension of considerable duration, in addition to which they commonly complain either of muscular weakness or of paralysis of an intermittent or recurrent nature. In association with metabolic alkalosis, the carpal and pedal spasm of tetany is frequently seen, and Trousseau and Chvostek signs may be elicited. Other interesting findings are polyuria and polydipsia, phenomena which are in consonance with earlier observations that chronic administration of mineralocorticoids results in a "diabetes-insipidus-like" picture. The usual aldosteronism complex does not include edema, but excessive aldosteronism has been found associated with edema. The authors present observations on 5 patients with aldosteronism, 4 of whom were operated on. In the 5th patient the diagnosis of aldosteronism seemed proved by the fact that the excretion of aldosterone was about 10 times the normal range. Two of the patients had benign tumors, 1 had carcinoma, and 1 had hyperfunction without tumor. Aldosterone excretion ranged from 8 mcg. per 24 hours in one patient with adrenal adenoma to 180 in the presence of a metastasizing adrenal carcinoma.

In 2 patients the administration of corticotropin (ACTH) caused a striking increase in aldosterone excretion. This observation seemed to refute the idea that the response to ACTH might be used to differentiate hyperplasia from tumor, because a 10-fold increase was produced by ACTH in a patient with a highly malignant tumor. In 2 of 3 patients the addition of potassium to the diet caused an increase in aldosterone output. This may be of diagnostic value in patients in whom the basal value is in the borderline range. Although aldosterone may be mobilized by potassium administration, it is possible to produce positive potassium balance in these patients with rapid reversal of alkalosis, hypopotassemia, and electrocardiographic changes. Failure to restore potassium balance before operation involves an unnecessary surgical hazard. Furthermore, because of the synergistic effect of potassium deficiency and curare-like compounds, curare preparations should not be used in the anesthesia of patients with aldosteronism.

A transabdominal approach is suggested for exploration, because aldosterone-producing tumors may be very small, and the contralateral atrophy which is seen in pituitary basophilism (Cushing's disease) is absent. Diagnostic problems may arise from the fact that other mechanisms can cause hypopotassemic alkalosis. Two of the cases presented illustrate the occasional effects of chlorothiazide and of chronic abuse of cathartics in the genesis of clinical potassium depletion. The determination of urine pH and salivary sodium/potassium ratio have not been helpful. Such cases emphasize the necessity for specific aldosterone determinations.

NEUROLOGY & PSYCHIATRY

Progressive Muscular Dystrophy: Genetic Relation with Creatinine Metabolism. D. Brage and I. Noviski. Rev. Asoc. méd. argent. 73:333-336 (Sept.) 1959 (In Spanish) [Buenos Aires].

Two brothers, 16 and 14 years old, were observed in the Hospital Alvear of Buenos Aires. The patients had been normal up to the age of 7 years, after which they started to complain about numbness, pain, and marked weakness of the legs and the arms. The patients became unable to walk and to use the arms at the age of 11 years. The symptoms were typical of progressive muscular dystrophy of the Leyden-Moebius type. Only the muscles of the face and neck and certain muscles of the thorax were spared. No causal spinal lesion was found by neurological examination as causal factor of the disease. The metabolism of creatinine was unbalanced in both patients. It was normal in all members of the family (parents, grandparents, brother, and sister). A sister of the mother had suffered with the same muscular disease; she died at the age of 24 years. The authors conclude that progressive muscular dystrophy of the Leyden-Moebius type is a recessive hereditary disease due to a familial inbalance of the metabolism of creatinine.

A Method of Treatment for Delirium Tremens. R. Cantoni and M. Burner. Schweiz. med. Wchnschr. 89:1111-1113 (Oct. 17) 1959 (In French) [Basel, Switzerland].

The authors report on 30 patients, between the ages of 33 and 61 years, with delirium tremens, who were admitted to the psychiatric clinic of the University in Lausanne, Switzerland, in 1958 and were treated by a standardized method. They were given a slow intravenous injection of a mixture of 40% solution of fructose, strophantin, acetylmethionine, and vitamin C, followed immediately by an intramuscular injection of hepatic extracts. At intervals of 8 and 16 hours the patients were given again an intravenous injection of 40% solution of fructose. This treatment had been instituted for a 24-hour period and was repeated daily for the duration of the psychotic attack and for 24 hours after its termination. During the full length of the attack the daily fluid intake of the patients was limited to 1,500 to 2,000 cc., with the exception of extremely dehydrated patients. In certain cases, when it appeared necessary to employ sedatives, the patients were given promethazine in small doses. The use of opiates, tranquilizers, and barbiturates was entirely abandoned because of the dangers associated with the administration of these drugs during attacks of delirium tremens. All forms of restraint were omitted. The authors attempted to utilize the suggestibility of the alcoholic patients. A certain calmative effect, followed occasionally by sleep, was frequently obtained by suggestions aimed at inducing a hypnotic sleep. The results obtained with this therapeutic method were equal, and sometimes even superior, to those obtained by other methods of treatment, which are undoubtedly effective but are not always as harmless. Agitation, oneirism, and tremor were attenuated progressively and made way for a recuperative sleep. The average duration of the psychotic attack was 41 hours, the shortest period being 14 hours and the longest 75 hours.

Polyradiculitis. T. O. Iversen. Ugesk. laeger 121: 1562-1567 (Oct. 8) 1959 (In Danish) [Copenhagen].

The etiology and pathogenesis of polyradiculitis are unknown. Pathologically, a variable, but often considerable, number of nerve roots are the seat of infection or toxic degenerative changes, and not infrequently the whole axon is involved in the pathological process. Polyradiculitis may occur in combination with infectious diseases, especially mononucleosis. The symptoms depend on which and how many nerve roots are affected. The temperature is usually normal, both at the onset and during the course. Albuminocytological dissociation is the rule. Apart from the cases with respiratory paresis, the prognosis is usually good. Antibiotic treatment is thought to be without effect in the acute stage. In the Odense District and City Hospital, 17 patients (10 males and 7 females, 6 aged 15 years or less) with acute polyradiculitis were admitted during the last 4 years, most of them within 4 weeks after the onset of the symptoms. In 5 patients the symptoms set in with fever, but the temperature became normal within a few days. In 8 patients the sedimentation rate was elevated, varying from 15 to 87 mm. Changes in the spinal fluid were seen in 16 patients on the first puncture, and in 1 patient on repuncture a week later. Only 12 patients had primary albuminocytological dissociation on the first lumbar puncture; in the others there were varying changes with both increased albumin and cell count. There was no correlation between the clinical course and the changes in the spinal fluid. In 3 patients changes in the spinal fluid persisted in spite of marked improvement in the clinical condition, and 4 showed no signs of clinical improvement although the spinal fluid had become normal. On discharge, the condition of 13 patients was distinctly improved, in 3 the clinical condition remained unchanged, and 1 patient was transferred for further respirator treatment because of exacerbation with alarming respiratory paralysis.

GYNECOLOGY & OBSTETRICS

Vaginal Trichomoniasis: Influence of Pregnancy and of the Menstrual Cycle on the Incidence of T. Vaginalis Donné, 1837. M. P. Barreto, P. V. Oliveira, H. Zago Filho and others. Rev. Assoc. méd. brasil. 5:220-227 (Aug.) 1959 (In Portuguese) [São Paulo, Brazil].

In a previous paper, an abstract of which appeared in The Journal (171:2018 [Dec. 5] 1959), the authors reported on the role of Trichomonas vaginalis and of Candida species in the etiology of leukorrhea, as observed in a series of 593 women who had received a detailed gynecologic examination at the Mercy Hospital in Ribeirão Preto, Brazil.

In this article the authors report on the same group of patients in relation to the incidence of T. vaginalis as influenced by pregnancy and by the menstrual cycle. A series of 514 women were selected from the total number examined, and subdivided into 2 groups, one composed of 256 pregnant women, and the other of 258 nonpregnant, normally menstruating women. Investigations of T. vaginalis and of Döderlein's bacilli, as well as determination of the vaginal pH, were performed on all the patients. Infection with T. vaginalis was found in 40.7% of the nonpregnant women and in 39.8% of the pregnant.

T. vaginalis was present in 43% of the women in the first trimester of pregnancy, in 37.8% of those in the second, and in 35.5% of those in the third trimester. In the nonpregnant women, the incidence of infection with T. vaginalis was high (47.7%) during the menstrual phase; it increased (51%) in the immediate postmenstrual interval and dropped to a minimum (17.4%) in the postovulatory period. The average pH values showed parallel fluctuations, while the incidence of Döderlein's bacilli showed the opposite trend. The authors conclude that the variations in incidence of T. vaginalis, as correlated with the various phases of pregnancy and of the menstrual cycle, explain, at least in part, the discrepancies found in medical statistics regarding the frequency of trichomoniasis.

Folic-Acid Deficiency in Pregnancy: The Pathogenesis of Megaloblastic Anemia of Pregnancy. I. Chanarin, B. M. MacGibbon, W. J. O'Sullivan and D. L. Mollin. Lancet 2:634-639 (Oct. 24) 1959 [London].

The authors performed folic-acid clearance tests by following the rate of clearance from the plasma of a small dose of folic acid given intravenously to 241 pregnant women without anemia, to 11 pregnant women with untreated megaloblastic anemia, and to 30 healthy women who served as controls. The absorption of folic acid was studied by following the rise in the serum folic-acid level, after the oral administration of a small dose of the vitamin, in 90 healthy persons of both sexes, in 45 women who were between 20 and 40 weeks pregnant, and in 10 pregnant women with treated megaloblastic anemia. The rate of clearance of folic acid from the plasma was increased in 66% of the pregnant women in late pregnancy and in all the patients with twin pregnancy. These findings justify the conclusion that the increased rate of clearance is due to folic-acid deficiency. This deficiency appears likely to be due mainly to the fetal requirement for folic acid exceeding the dietary intake, but impaired absorption of this vitamin during pregnancy may also play a part. The rate of clearance of folic acid from the plasma was even more rapid in patients with megaloblastic anemia of pregnancy. The high incidence of this anemia in women with twin pregnancy and its onset in late pregnancy suggest that the factors producing folic-acid deficiency in women with normal pregnancy are responsible for the more severe folic-acid deficiency in patients with megaloblastic anemia. Since the absorption of folic acid appeared to be most impaired in the patients with megaloblastic anemia, this may contribute to the development of the more severe grade of folic-acid deficiency found in these patients. The dietary intake of folic acid may also be important.

Nonfatal Pulmonary Amniotic Embolism: An Unusual Transplacental Path of Entry. L. P. Cawley, R. C. Douglass and C. L. Schneider. Obst. & Gynec. 14:615-620 (Nov.) 1959 [New York].

A multiparous 37-year-old woman, with a 10-year history of neurosyphilis and of psychosis, was transferred to the Wayne County General Hospital in Eloise, Mich., with recurring grand mal seizures associated with a "term pregnancy one week before delivery." Pulmonary *amniotic fluid embolism* was diagnosed post partum from the symptoms of dyspnea, orthopnea, hypotension, cyanosis, hemoptysis, elevated venous pressure, and transient sequential roentgenographic and electrocardiographic changes. The diagnosis was supported by the observation of heavy soiling of the amniotic fluid with meconium and the finding of a transplacental channel which could have provided a ready pathway for entry of amniotic fluid into the maternal circulation. Six months after delivery the patient died of an intercurrent disease. No residual traces of pulmonary emboli, of amniotic debris, or of pulmonary vascular sclerosis were found at autopsy. These observations suggest that such debris is subject to phagocytic action and histolytic digestion with resolution of the vascular occlusions, thus leaving little or no late traces that are demonstrable histologically. Clinically, there was mild transient "obstetric shock," and this is adequately accounted for by the production of acute cor pulmonale by disseminated pulmonary embolism of formed debris from amniotic fluid.

The Use of a Tranquilizer Drug in Childbirth. E. W. Lander. Southwestern Med. 40:704-705 (Nov.) 1959 [El Paso, Texas].

Prospective mothers should be taught that there is nothing pathological about normal labor and that complications are exceptional. The naturalness of childbirth should be stressed, with the idea of eliminating on minimizing fear. A simple explanation of the mechanism of labor, what the patient may expect and what will be expected of her, may be interjected at visits during the third trimester.

A mother should be permitted to have her baby with no anesthesia, except for complicating circumstances which dictate the procedure. The use of general anesthesia for the actual delivery is all too often the desire of the physician rather than the patient.

The action of certain of the tranquilizer drugs is ideal in obstetrics, in that they induce relaxation and tend to minimize the fear of labor. The phenothiazine derivatives, such as chlorpromazine and promazine, have been used successfully, but with occasional undesirable complications. Perphenazine (Trilafon) is one of the newer drugs in this category which, in therapeutic dosage, is relatively free of toxicity; at the same time, it is 5 to 10 times more potent. The author used Trilafon chiefly in primiparas but also in multiparas with histories of hard labor or long interval since last childbirth. One 8-mg. tablet of Trilafon was given orally, usually on admission to the hospital, although a few multiparas have been given a tablet beforehand, to be taken at home as soon as they felt that labor has started. The serenity and composure of these patients during labor have been striking. On being questioned 24 hours post partum, they were all uniformly pleased with their labor experience. Moreover, there have been no visible adverse effects on the newborn infant. The use of additional analgesia has been minimized during childbirth. The majority of women received only one injection, consisting of Nisentil (30 mg.) and Lorfan (0.5 cc.) in the terminal phase of the second stage. The majority have delivered spontaneously without any further anesthesia or with only a few whiffs of Trilene.

Fetal Death in Utero. J. A. Pritchard. Obst. & Gynec. 14:573-580 (Nov.) 1959 [New York].

The author delineates a regimen for managing the patient with intrauterine retention of a dead fetus. Observations on 100 women with a dead fetus which had been retained for one or more weeks indicate that the patient is unlikely to develop potentially dangerous hypofibrinogenemia in less than 5 weeks after the fetal death. However, one out of 4 women who retained a dead fetus in utero for 5 or more weeks developed potentially dangerous hypofibrinogenemia. Hypofibrinogenemia, prior to delivery, may be asymptomatic, or there may be clinical evidence of abnormal hemostasis. Fibrinogen administration without emptying the uterus results only in a transient elevation of the level of circulating fibrinogen. The administration of fibrinogen may not infrequently result in homologous serum hepatitis. Labor, either spontaneous or induced with oxytocin, does not result in further fibrinogen depletion. A number of patients who carry a dead fetus in utero for a prolonged period of time develop anxiety states, which cause considerable distress and have been difficult to eradicate completely. It is recommended that the patient with a dead fetus be observed for 3 or 4 weeks after the fetal death. During this time she will probably go into labor and deliver without difficulty. If she has not delivered at the end of this period, the uterus should be evacuated.

DERMATOLOGY

The Disease Called "Wildfire." C. E. Counter. A. M. A. Arch. Dermat. 80:391-397 (Oct.) 1959 [Chicago].

The author reports on 47 consecutive patients with a disease closely resembling exfoliative pemphigus, who were admitted to the Pemphigus Hospital of Mato Grosso, Brazil. The Brazilian expression "fogo selvagem," applied to this endemic disease of central South America, literally means uncontrolled fire, in much the same way that the word "wildfire" brings to mind a fire that has got out of control in dry grass. The patients truly experienced a burning feeling that continued uncontrolled for days and months; only when they were completely quiet did they get any degree of relief. The patients were between the ages of 10 and 30 years when the symptoms began, and the disease might last 15 years or longer. Typically, the first lesion was a vesicle on the central part of the face or on the upper part of the chest; other vesicles and bullae soon developed over the face and upper trunk; often lesions involved the whole trunk and the extremities and even the scalp. Mucous membrane surfaces lining the various orifices were not involved. As the bullous lesions became more numerous and extensive, an exfoliative dermatitis developed. There was a distinct odor of dried serum, which was the distressing repulsive feature of the disease. Of the 47 patients, the disease was subacute in 2, chronic in 43, and ill-defined in 2. In the 43 patients with chronic disease, the disease was further classified as bullous exfoliative in 24, pustular and ulcerative in 5, intensively foliaceous in 9, herpetiform in 2, verrucous in 2, and hyperpigmented in 1.

Treatment of this odd disease with quinacrine hydrochloride given orally produced regressions in 87 (58%) of 151 patients treated at the Instituto Ademar de Barros in Mandaqui, São Paulo, Brazil. Quinacrine is known to produce improvement in diseases showing intolerance to sunlight, such as chronic discoid lupus erythematosus and polymorphic light-sensitive eruption. The treatment of the patients in the Pemphigus Hospital of Mato Grosso consisted chiefly of hydrotherapy followed by the application of a tar preparation. Repeated 3 times a week, it brought about a rather permanent arrest of the disease. At least 56.5% of the patients treated with the tar preparation had their disease arrested or improved sufficiently to be treated at home and to obtain their complete arrest of pemphigus. The patients seemed to value the relief from itching and from the odor even more than the cure possibilities. It may be that the chief value of baths and tar-compound applications for patients with the Brazilian type of pemphigus foliaceus is its ability to produce hyperpigmentation.

Clinical Features of Contact Dermatitis Due to Neomycin: Report of Cases. H. Reynolds, J. F. Hildebrand, C. S. Livingood and R. P. Fosnaugh. A. M. A. Arch. Dermat. 80:455-460 (Oct.) 1959 [Chicago].

The authors report on 10 male and 18 female patients, between the ages of 5 and 65 years, in whom a diagnosis of contact dermatitis due to neomycin was made. With the exception of 3 patients, the development of neomycin sensitivity was an insidious process. In these 3 patients there was a definite correlation between the use of a neomycin-containing preparation and the onset of an acute exacerbation. Most of the other patients were suspected of neomycin sensitivity because of a gradual progression of their eruption and failure to respond to what would be considered adequate therapy. In this group there was no clear-cut relationship between use of a neomycin-containing preparation and progression of dermatitis. The use of neomycin did not cause an acute exacerbation. In 2 patients, one with an eczematous dermatitis and the other with otitis externa, the use of a neomycin-containing topical preparation caused an exacerbation, which was interpreted at the time as being a flare-up of the underlying dermatitis.

An analysis of the primary sites of involvement, including feet, ears, hands, axillas, eyelids, and perianal region, would seem to support the clinical impression that sensitization may be more apt to occur if the involved site is an intertriginous area, or subject to maceration. However, the predominance of otitis externa (in 9 of the 28 patients) may only be a reflection of the widespread use of neomycin-containing topical steroids in this situation and chronicity of the problem. It is felt that neomycin contact sensitivity is not common. The onset may be insidious, and despite an increased index of suspicion on which recognition depends, rather than on the appearance of the classical signs of acute contact dermatitis, only 3 cases have been observed by the authors in the past. The possibility of such sensitivity should, however, be borne in mind, especially in a patient with an eczematous dermatitis, who is using a neomycin-containing preparation and who is not responding satisfactorily. In all the patients, symptoms and signs regressed promptly after withdrawal of neomycin.

UROLOGY

Analysis of 51 Patients with Horseshoe Kidney. J. F. Glenn. New England J. Med. 261:684-687 (Oct. 1) 1959 [Boston].

Horseshoe kidney is one of the more common congenital urologic anomalies, occurring once in every 400 or 500 births. The literature deals mainly with the surgery and with the various grave complications secondary to the anomaly, but fails to reveal any adequate long-term follow-up study of patients with horseshoe kidney. The author studied 51 consecutive patients (28 males and 23 females) with horseshoe kidney seen at Duke Hospital, Durham, N. C., over a 25-year period, 1933 to 1958. Pain or signs of urinary-tract infection were the predominating symptoms. Horseshoe kidney was an incidental finding in almost a fourth of the patients. The initial diagnosis was made radiologically in 82.3%, at autopsy as an incidental finding in 11.8%, and clinically in 5.9% (with subsequent radiologic confirmation).

Thirty-one patients were followed for from 1 to 22 years (an average of nearly 10 years); the remaining patients had died (6) or were lost to follow-up. Eighteen of those followed for prolonged periods remain asymptomatic and without complications at this time. Five of the other 13 patients are known to have renal calculi, 4 have persistent infection, and 4 have Rovsing's syndrome (nausea and vomiting and abdominal pain accentuated by hyperextension). The long-term follow-up indicates that the complications of infection may be controlled by conservative measures in many cases. Hydronephrosis and calculus formation were quite common and were the indications for surgical treatment in 12 of the patients. Successful surgery depends upon correction of the anatomic deformity by division or resection of the isthmus, nephropexy, and pyeloplasty. Surgery for relief of pain has been condemned, and was not utilized in any of these patients. While horseshoe kidney is thought to occur more commonly in young persons, the patients in this series, at the time of diagnosis, were of an average age of 34 years, and only 7 were less than 7 years old.

Tumors of the Renal Pelvis: Review of Sixty-Four Cases. A. B. Seth-Smith. Brit. J. Urol. 31:265-276 (Sept.) 1959 [Edinburgh].

This report is based on the records of 64 patients with primary tumor of the renal pelvis, treated at the London Hospital during the 48 years up to December, 1956. Full clinical information is lacking in a few cases. Fifty patients underwent surgical treatment of some kind, the condition of the remainder being either too advanced for such treatment or undiagnosed during life. The group included 12 cases of papilloma without invasion or cellular malignancy; 23 cases of papillary carcinoma, in 4 of which there was no invasion, while 19 showed local or general spread; and 29 cases of solid carcinoma. The high incidence of solid infiltrating growth (45%) was unusual, because these tumors, particularly the squamous-cell ones, are becoming less common. In contrast, 5 out of 12 cases of papilloma occurred in the last 6 years under review. The papillary growths which show no evidence of malignancy have been grouped separately, and it is suggested that the prognosis may be relatively favorable in this group. Results of treatment in the other groups are largely disappointing, and among those with solid tumors no 5-year survivals are to be found. Only on very few occasions was primary nephroureterectomy done, and it is possible that this affected the prognosis badly in some of the cases.

It is generally accepted that these tumors cannot be differentiated from one another with any degree of accuracy by histological examination. Solid growths may be composed of transitional, spheroidal, columnar, or squamous cells, alone or in combination, and those which appear papillary on the surface frequently contain areas of squamous-cell carcinoma. Classification, therefore, is bound to be somewhat arbitrary and should be restricted to broad outlines. However, differentiation between papillary and nonpapillary tumors has stood the test of time, and now there is no doubt that the papillary tumors carry a better prognosis. Nevertheless, the contention that squamous and papillary tumors are entirely unrelated appears to be misleading. There are many similarities between tumors of the bladder and those of the renal pelvis; yet in the bladder the papilloma is usually kept separate from the more malignant tumors, because the outlook after treatment is relatively favorable. Bladder papillomas can grow to great size without being considered malignant. It is interesting to speculate whether urinary carcinogens are a factor in producing tumors of the mucous membrane with which they come into contact, but there is as yet little evidence of this. Bilateral tumors occurred once in this series, but they are remarkably rare. In this series, calculi were present in almost half of the cases of solid tumor and in 1 out of 7 of the papillary ones, a similar incidence to that reported by others. Renal anomalies, stasis, infection, and calculi may play a part in causing papillary as well as squamous tumors.

Torsion of Testis. G. Fahlström and H. Johansson. Nord. med. 62:1486-1487 (Oct. 8) 1959 (In Swedish) [Stockholm].

Torsion of the testis, most frequent before the age of 20 years, is an acute surgical disease requiring attention within the first hours. Testes in the scrotum are affected as often as undescended testes. Intracapsular torsion, often bilateral, depends on a malformation which allows the testis increased motility; extracapsular torsion is, as a rule, due to trauma, and here no other malformation than possible retention of the testis is a contributing factor. The onset is usually marked by acute pain, localized in the affected testis, often almost like kidney colic, sometimes with vomiting. In cases with less pronounced pain, diagnosis is more difficult. Eight cases are described in patients, aged from 2 to 19 years. In 3 of these, exploration revealed a gangrenous testis; in one case exploration resulted in the diagnosis of epididymitis. In 2 of the 4 patients treated surgically, operation was delayed because of mistaken diagnosis; in both patients there was disturbance of nutrition, with gangrene. The prognosis depends on how intensive the nutritional disturbance is and how early surgical treatment is instituted. The difficulty in diagnosis justifies exploration in uncertain cases. The most frequent mistaken diagnosis is that of acute epididymitis. Irreversible changes occur in testicular torsion after a short period of strangulation.

Kidney Transplantation from a Nonidentical Twin to Another After Irradiation of the Entire Body of the Recipient: Satisfactory Kidney Function Four Months After Transplantation: Preliminary Report. J. Hamburger, J. Valysse, J. Crosnier and others. Presse méd. 67:1771-1774 (Oct. 17) 1959 (In French) [Paris].

The authors report a 37-year-old man with chronic disease of the kidneys which had progressed to terminal renal insufficiency. The man was given 2 sessions (6 days apart) of cobalt radiation of the entire body with a total dose of 460 r. The day after the second radiation treatment the transplantation of the kidney on the left side was performed. The donor was the twin brother of the recipient. The nonidentical characteristics of the 2 brothers were established by clinical and biological findings. The patient was kept in a strict aseptic environment, beginning the day of the first radiation, for a period of one month in order to avoid infection during the phase of aplasia of the blood and the bone marrow due to cobalt radiation. During the first 15 days after the operation, the function of the transplanted kidney was satisfactory. In the third week a sudden critical period of renal insufficiency occurred. This subsided in the fourth week, with return to normal renal function, disappearance of signs and symptoms of uremia, and disappearance of the retinal lesions. Four months after the kidney transplantation the general condition of the patient was excellent.

The factors which may have played a part in the success of the transplantation are: (1) the condition of chronic renal insufficiency of the recipient;

(2) the radiation treatment; and (3) the close relationship between the donor and the recipient. The hypothesis of a synergic action of these factors is advanced as a possible explanation of the success. Perhaps the critical period in the third week after transplantation may be interpreted as the first recovery from the immunological disease which usually provokes the rejection of the transplant. If the idea is correct that this disease is not irreversible, new prospects are opened in the field of kidney transplantation.

Some Common Complications After Prostatectomy. J. C. Ross and L. F. Tinckler. Brit. M. J. 2:663-666 (Oct. 10) 1959 [London].

While postoperative complications have always developed in a certain percentage of patients undergoing prostatectomy, now, with the increasing age of the patients and the number who have intercurrent medical conditions, these are likely to become more frequent. The authors investigated complications arising in 100 prostatectomies, the patients being unselected. Wilson Hey prostatectomy was carried out in 65 cases, retropubic prostatectomy in 3, and cold-punch resection (perurethral) in 32. The type of operation apparently makes no essential difference as to the incidence of complications. With modern methods of anesthesia, the danger period of prostatectomy has shifted from the actual operation to the first few postoperative weeks. The authors are not concerned with immediate or reactionary hemorrhages, as modern operations, including perurethral resection, appear to cope fairly successfully with hemorrhage. Osteitis pubis did not develop in any of the patients. The postprostatectomy flap or valve is rarely encountered now that operation is carried out under direct vision and trigonectomy is performed.

A temporary incontinence was noted in approximately a quarter of the present series. A simple method of "sphincterometry" was used in the assessment of this incontinence. Postmeatal stricture appears to have been largely eliminated by discarding the red rubber catheter. With the use of a latex catheter, a urethral stricture developed in only 2% of the patients. Postoperative infection continues to be the most obstinate problem, Escherichia coli and Proteus vulgaris preponderating. It is suggested that back-pressure and hydronephrosis before operation are factors in encouraging infection. It is also pointed out that the peak period of infection occurs during the first 4 weeks, during which the prostatic cavity is in the process of epithelizing. The incidence of epididymitis with vasostomy was 7% in this series. A temporary suprapubic leak occurs in a proportion of patients, and is probably due to a lack of healing ability in elderly and debilitated patients.

THERAPEUTICS

Treatment of Pemphigus Foliaceus with Triamcinolone: New Personal Cases. T. A. Furtado and G. Batista. Hospital 56:657-664 (Oct.) 1959 (In Portuguese) [Rio de Janeiro].

Three patients with pemphigus foliaceus obtained complete regression of their lesions with triamcinolone, and the authors accordingly applied the same therapy to another 10 patients. The latter included 9 women and 1 man, between the ages of 10 and 28 years, except for one who was 43 years old. The cutaneous manifestations and the general condition in 7 patients were pronounced. There was impairment of joint function, intense sensation of burning, and pruritus. The shortest duration of the disease was 1 month; the longest was 10 years. Triamcinolone was given in an initial dose of 32 mg. daily to 7 patients, and of 16, 36, and 48 mg., respectively, to the other 3. The total dose administered varied between 180 mg. and 2.88 Gm., and the daily maintenance dose ranged from 4 to 8 mg.

Within a period of 34 to 166 days all 10 patients obtained clinical recovery, including improvement in the general condition and, in some patients who had become amenorrheic, return of the menstrual cycle. No relationship was found between duration of the disease and response to treatment, although the generalized forms with intense bullous, exfoliative lesions required a higher daily dosage. Reduction of the dose to a maintenance amount of 4 to 8 mg. was possible in a short time. Although some patients had a relapse during the treatment, no recurrence was observed after clinical recovery had been achieved. The drug was well tolerated. Only one patient developed a "full-moon face." A second patient manifested a mild euphoria. The authors believe that triamcinolone is the choice corticosteroid for treatment of pemphigus foliaceus. Although the effect is palliative and not curative, the administration of small maintenance doses permits the patients to remain free from symptoms and to resume a normal life.

Treatment of Progressive Protopathic Muscular Dystrophy with Group-Specific Extracts Derived from the Gastric Mucosa of Hogs. B. Manzini and L. Frattola. Minerva med. 50:3240-3242 (Oct. 13) 1959 (In Italian) [Turin, Italy].

The authors report on the effect of some group-specific extracts derived from the gastric mucosa of hogs on 21 patients, 3 female and 18 male, 10 to 52 years of age, with progressive protopathic muscular dystrophy. The extracts, which contained both a nonacid polysaccharide and an amino acid, were administered in tablets of 100 mg. each, 2 to 3 tablets per day, to each patient for a period of one month. The extracts had a beneficial effect on the kinesthesis of each patient. In some patients the muscular strength improved; one patient, who before the treatment had to interrupt his work every 20 to 30 minutes, after 20 days of treatment was able to do manual work uninterruptedly for longer periods of time; another patient was able to change from a sitting position to a standing one with the need of no support; a third patient, in the last phase of the treatment, was able to walk without falling, as used to happen before the treatment. The body weight increased in all but one patient who during the treatment suffered from bronchopneumonia. The values of the aldose activity of most patients declined to below normal. The decline was already present during the first days of treatment. Tests made in 5 patients 3 months after the treatment showed that the aldose values had increased again and that in 3 patients they were higher than the values recorded at the beginning of the treatment; loss of body weight was also noticed at this time. The transaminase values, checked in 14 patients, increased moderately after the administration of the extracts but with no apparent relationship to the course of the disease. The authors believe that progressive protopathic muscular dystrophy may be related to an early deficiency of anabolic endogenous factors.

Therapeutic Value of Sulfamethoxypyridazine in Some Internal Infections. A. Legramante and A. Perrone. Minerva med. 50:3237-3239 (Oct. 13) 1959 (In Italian) [Turin, Italy].

The authors report on the effect of sulfamethoxypyridazine on 71 patients with infection of the urinary tract or of the respiratory tract, on 10 patients who had previously suffered from rheumatic disease and were in need of antistreptococcic prophylaxis, and on 48 patients to whom the drug was given prophylactically before tonsillectomy, tooth extraction, and lymph node, kidney, or liver biopsy. A dose of 2 to 3 Gm. of sulfamethoxypyridazine was given on the first day, and a dose of 1 to 1.5 Gm. the following days. The drug was well tolerated. The patients with bronchopulmonary or urinary infections received the drug in combination with antibiotics, and the results obtained were rapid and good. Good results were obtained in 30 of 32 patients with severe pharyngotonsillar infection; 28 of these patients were treated with the sulfonamide only, one with the sulfonamide combined with tetracycline, and one with the sulfonamide combined with penicillin. Good results were also obtained in patients with chronic bronchitis who suffered from acute relapses and in patients with bronchiectasis. In patients with acute infections of the urinary tract, the drug was effective not only on gram-positive and gram-negative cocci but also on Escherichia coli and at times Pseudomonas aeruginosa.

Among 53 patients with urethritis, cystitis, and pyelonephritis, sulfamethoxypyridazine had a beneficial effect on 17 patients in whom the disease was caused by Esch. coli; these 17 patients, especially those with pyelonephritis, received the drug for more than 10 days. The drug had no effect on 6 of the remaining 36 patients; 2 were suffering from urethritis caused by Staphylococcus albus, 3 from cystitis and pyelonephritis due to Proteus organisms, and 1 from cystitis caused by Ps. aeruginosa. Good results were also obtained in those patients in whom sulfamethoxypyridazine was used as an antistreptococcic prophylactic of rheumatic disease or for general anti-infective prophylaxis before tonsillectomy, tooth extraction, or biopsies. In patients with rheumatic disease the administration of the drug was followed by a progressive decline, and in some cases even the disappearance, of the serum values of antistreptolysin.

First Clinical Research on the Anticholesterol and Antilipid Effect of a New Estrogen Derivative: 16-α-Chloroestrone 3-Methyl Ether. G. Annoni. Minerva med. 50:3084-3088 (Sept. 29) 1959 (In Italian) [Turin, Italy].

Some halogenated derivatives of estrone have a marked lipid reducing effect and a low estrogen effect; most active among these derivatives are those which are obtained by introducing an atom of iodine or chlorine in the 16-alpha position. The author reports on the effect of one of these derivatives, 16-alpha-chloroestrone 3-methyl ether, on 15 arteriosclerotic patients. Eight patients (3 male and 5 female) suffered from diffuse arteriosclerosis; 3 (2 male and 1 female) from myocardiocoronary arteriosclerosis; 2 (1 male and 1 female), from cerebral arteriosclerosis; and 2 (1 male and 1 female), from arteriosclerosis mainly of the lower limbs. Each patient received 5 mg. of the drug per day, given in 2 equal subdoses; the treatment lasted from 20 to 30 days. Results of laboratory tests showed a 15 to 40% decline in the level of total serum cholesterol in all but 2 patients. This decline was similar in the ester fraction and in the free fraction, in men as well as in women, and was more marked the higher the initial value of the cholesterol level; a 20 to 30% decline was observed in 9 patients.

The decline of the cholesterol level was already manifest on the 10th day of treatment and became most marked after 20 to 30 days of treatment. The cholesterol values tended to increase, though slowly, when the drug was withdrawn, and in 2 or 3 months they were comparable to the values recorded at the beginning of the treatment. One of the 2 patients whose serum cholesterol level was not affected by the drug was a 30-year-old obese man with diffuse arteriosclerosis; his father, too, presented high cholesterol and lipid values, and suffered from severe arteriosclerosis and diabetes. The second patient was a 60-year-old woman with arteriosclerosis and biliary calculosis of the cholesterol type. The drug in this instance had to be withdrawn after 20 days of treatment because of the recurrence, after 10 years, of a mild menstrual flux, which disappeared in 3 days. With the exception of these 2 patients, the values of total lipemia declined from 15 to 25% in all instances. The clinical results, though nothing definite can be said yet, were also good. The physical and psychointellectual conditions of the patients improved. With the exception of the 2 persons who derived no benefit from the drug, no other patients showed intolerance.

The author believes that the mechanism of action of 16-alpha-chloroestrone 3-methyl ether is not the same as that of the synthetic anticholesterol drugs derived from acetic acid. The undoubted anticholesterol effect of the drug is more marked than the antilipid effect. The drug has also an estrogenic effect that may become manifest clinically.

Hypercoagulation in the Course of Treatment with Anticoagulant Drugs. R. Raynaud, M. Brochier and A. Tadei. Presse méd. 67:1733-1734 (Oct. 10) 1959 (In French) [Paris].

Three types of hypercoagulation, "resistant," "provoked," and "dissociated," which were observed in some patients who were being treated with anticoagulant drugs, such as heparin or bishydroxycoumarin (Dicumarol), are discussed. The cases of 2 patients with resistant hypercoagulation —the first, a 35-year-old woman with mitral disease, who did not respond to heparin given by continuous perfusion in a dose of 500 to 600 mg. per day, and the second, a 45-year-old man, who had suffered repeatedly for 5 years from phlebitis and who did not respond to a large dose (1.050 mg.) of ethyl biscoumacetate (Tromexan Ethyl Acetate), to heparin, or to both drugs given in combination —are presented. The authors believe that thrombophilia in these 2 patients was due to the presence of an excessive amount of thromboplastin and platelets in the blood; coumarin derivatives have very little effect in such instances. Good results can be obtained, however, as was shown in a third case reported, if heparin is associated with Dicumarol or if the dose of Dicumarol is increased. It was observed in this third patient that at a certain moment the hypercoagulation "let down," and then it was possible to withdraw heparin.

Provoked hypercoagulation may occur either as the result of a faulty anticoagulant treatment or in the course of a nonfaulty treatment. The case of a patient, 78 years of age, in whom hypercoagulation was provoked by the withdrawal of heparin, which was to be substituted with Dicumarol, is presented. The condition of this patient improved as soon as the heparin therapy was reinstituted. A faulty treatment, in cases of patients who are receiving Dicumarol only, may be the result either of a too high initial dose or of the sudden withdrawal of the anticoagulant. The cases of 2 patients, 50 and 18 years of age, respectively, who suffered from provoked hypercoagulation despite a nonfaulty treatment, are presented. This form of hypercoagulation is observed almost exclusively during treatment with coumarin derivatives. In these 2 patients at first the prothrombin values, the heparin test, and even thromboelastography indicated good hypocoagulation; in a few days, however, the results of the tests and especially of thromboelastography became less satisfactory, indicating that the treatment had provoked hypercoagulation. In the latter case it seemed that the coumarin derivatives provoked, paradoxically, [illegible] nd that they neutralized the [illegible] of heparin.

The last form of hypercoagulation in the course of treatment with anticoagulant drugs, dissociated hypercoagulation, is evidenced by a dissociation between the results of the prothrombin values and of the heparin tolerance test or of the thromboelastogram, as well as dissociation between the vertical and horizontal data of the thromboelastogram. The authors believe that only thromboelastography can give reliable evidence of the effect of treatment with anticoagulants in patients with progressive thrombosis, and of the possible appearance of thromboembolic accidents in the course of properly carried out treatment with anticoagulants.

PATHOLOGY

Isolation of Measles Virus at Autopsy in Cases of Giant-Cell Pneumonia Without Rash. J. F. Enders, K. McCarthy, A. Mitus and W. J. Cheatham. New England J. Med. 261:875-881 (Oct. 29) 1959 [Boston].

Giant-cell pneumonia, often referred to as Hecht's giant-cell pneumonia, is an interstitial pneumonitis that has so far been observed only in children. It is characterized by the presence of multinuclear giant cells with intranuclear and intracytoplasmic inclusion bodies. Additional pathological features are a preponderance of mononuclear cells in the infiltrate, squamous metaplasia of the bronchial and bronchiolar epithelium, proliferation of alveolar lining cells, and the occurrence in occasional cases of giant cells in organs other than the lungs. The etiological agent has remained obscure. No bacterial species has been found causally associated with the pneumonic process. The viruses of canine distemper and measles have both been suggested, principally because they induce the formation of giant cells with characteristics resembling those present in this type of pneumonia.

The authors report observations on 3 girls, 2 to 4 years of age, who were admitted to the Children's Hospital in Boston with chronic debilitating diseases. The diagnosis of giant-cell pneumonia was made restrospectively upon histological examination of lung tissue obtained at autopsy. The chronic diseases existing in these children were mucoviscidosis, leukemia, and Letterer-Siwe disease respectively. None of the children had signs or symptoms of measles during their illnesses, although one of them had been exposed to 2 siblings with measles.

The evidence presented appears to justify the conclusion that the viruses isolated post mortem from pulmonary secretions or tissue of 3 typical cases of giant-cell pneumonia (Hecht) are indistinguishable from the virus of measles. The evidence consists of similarity or identity of cytopathogenic properties, growth characteristics, infectivity for macaco monkeys, lack of pathogenicity for suckling mice and chick embryos, and antigenic composition. It, therefore, seems justifiable to conclude that measles virus was the etiological agent in the 3 cases of giant-cell pneumonia. Although this number is small, the authors believe that it is sufficient to indicate that, in at least a proportion of cases of giant-cell pneumonia, measles virus will prove to be the responsible agent.

Persistence of Measles Virus and Depression of Antibody Formation in Patients with Giant-Cell Pneumonia After Measles. A. Mitus, J. F. Enders, J. M. Craig and A. Holloway. New England J. Med. 261:882-889 (Oct. 29) 1959 [Boston].

The authors present the results of studies on 4 leukemic children with measles complicated by severe pneumonitis. From 2 of these patients with pneumonitis that followed the subsidence of signs of measles, agents identified as measles virus were isolated. The virus was also recovered from tissues taken at autopsy. The diagnosis of giant-cell pneumonia was made provisionally during the course of the illness and confirmed after death. Measles virus persisted for an unusually long period in the upper respiratory tracts of these patients, who also failed to respond in the normal manner by development of specific antibodies. The clinical and pathological features of the pneumonitis were indistinguishable from those found in the patients described in the preceding paper, with giant-cell pneumonia not associated with overt measles.

In the other 2 patients with pneumonitis after measles who survived, measles virus was found to persist for unusually long periods in one, and the antibody response appeared to be depressed in both. Accordingly, it is probable that giant-cell pneumonia was also present in these 2 children. Laboratory diagnostic methods now available permit the clinical recognition of giant-cell pneumonia caused by measles virus. To make this diagnosis appears important, especially regarding therapy and prevention. Since the 2 surviving patients in this study received large quantities of measles antibody, it is possible that seroprophylaxis and serotherapy will prove effective. The survival of 2 patients who received large doses of gamma globulin at the time of exposure suggests that this material may be of value in modification of subsequent measles pneumonitis. Furthermore, it is possible that very large quantities of antibody administered intravenously in the form of measles convalescent plasma will mitigate this condition, since rapid recovery in one case followed this procedure. Abnormal responses on the part of leukemic children to infection with measles is also of interest.

Chronic Pyelonephritis Lenta and the "Malignant Phase of Hypertension." O. Saphir and N. A. Cohen. A. M. A. Arch. Int. Med. 104:748-762 (Nov.) 1959 [Chicago].

The authors report on 25 Negro and 10 white patients, between the ages of 29 and 78 years, with the malignant hypertension syndrome, who died in the Michael Reese Hospital, Chicago, and whose autopsy protocols have been reviewed with special reference to gross and microscopic changes in the kidneys. In contrast to previous autopsy reports in the literature, in which the kidney lesions of most patients with malignant hypertension were ascribed to "malignant nephrosclerosis," the authors emphasize that malignant nephrosclerosis as one pathological entity does not exist. By means of established criteria, a diagnosis of pyelonephritis lenta was made in 27 of the 35 patients, and a diagnosis of glomerulonephritis combined with pyelonephritis lenta was made in the remaining 8 patients. By pyelonephritis lenta is meant, in contrast to destructive pyelonephritis, a slowly developing inflammation of the kidney involving principally the pelvis, tubular apparatus, and interstitial tissue, in the absence of suppuration. Most likely, because of the involvement of the interstitial tissue, the arteries of the size of the intracortical and arcuate vessels become secondarily affected, in the form of an endarteritis deformans with severe narrowing of the lumen. As in Goldblatt's experiments, these changes are probably responsible for the hypertension.

The clinical aspects of the 27 patients with pyelonephritis lenta were notable in that most of them were without a clinical history of typical or classical pyelonephritis. However, in 2 patients who had been previously hospitalized for diverse reasons, there was unequivocal laboratory evidence of urinary tract disease long before the onset of hypertension. In contrast, the 8 patients in whom glomerulonephritis was one factor in the picture of malignant hypertension generally had clinically known long durations of renal disease before the onset of hypertension. These findings show that the clinical course of pyelonephritis lenta is insidious, often silent ("lenta"), until the severity of the lesions of the blood vessels causes hypertension. The cause of pyelonephritis lenta and whether or not it is blood-borne or "ascending" are not known. Most likely the disease is the result of an insidious bacterial infection spreading to the interstitial tissue of the kidneys. The malignant phase is ushered in by a superimposed element appearing either very early or late. Impending myocardial failure, glomerulonephritis, acute pyelitis, acute pyelonephritis, infarcts of the kidney, or chronic progression of the intrarenal changes, proceeding to a stage responsible for renal failure, may constitute this second factor. Arteriolar necrosis cannot possibly usher in the malignant phase, since it is obviously a very recent phenomenon, occurring only after renal failure has been established.

Thoracic Choriocarcinomas. P. Thibault. Presse méd. 67:1892-1895 (Oct. 31) 1959 (In French) [Paris].

Choriocarcinomas are either primary and mediastinal or, more often, metastatic and pulmonary. They occur in both women and men. In women, they are gestational or nongestational. In men, they probably represent a nonabsorbed or undeveloped puberal element that under some hormonal stimulation develops into a tumor. The development of gestational choriocarcinomas usually occurs in the weeks after a mole, a nonmolar abortion, or even an apparently normal delivery. As the neoplastic elements migrate through the blood, the lungs form their first barrier, and pulmonary metastases occur in almost 100% of the patients. Cough, extensive and frequent hemoptysis, and roentgenologic findings of round, multiple, and bilateral pulmonary images are characteristic signs of pulmonary metastases which occur within a short interval after the gynecologic manifestations. These signs and symptoms, together with a high rate of prolan B, indicate nearing death even if the pulmonary nodules may regress. Nongestational choriocarcinomas in women are secondary to an ovarian embryoma. They usually occur between the ages of 14 and 23 years. Abdominal pain and hormonal manifestations, such as metrorrhagias, acceleration of puberal development, menstrual disorders, excessive urinary gonadotropins, and positive Aschheim-Zondek reaction, are the main symptoms. In some exceptional cases the origin may be epiphysial. The pulmonary signs and symptoms as well as the fatal course of these tumors are similar to those of the gestational choriocarcinomas.

All the mediastinal choriocarcinomas reported to date have occurred in men, with one exception only. These tumors are usually observed in men, between the ages of 15 and 35 years. The intrapulmonary forms are almost always secondary. The intramediastinal forms are almost always primary and have a complex dysembryonic structure in which the choriocarcinomatous element is only one of the components. Approximately 130 cases of thoracic choriocarcinomas in men have been reported—102 pulmonary and 28 mediastinopulmonary. The pulmonary type is the result of an early blood afflux from a partially or entirely carcinomatous focus. The original focus was testicular in 67 of the 102 patients reported, mediastinal in 21, and epiphysial in 1. The mediastinal choriocarcinoma is usually a heteroplastic dysembryoma. Besides the symptoms observed in women with these tumors, in men the mediastinal or the mediastinopulmonary forms include a syndrome of compression of the superior vena cava with hemorrhagic or serous pleural exudation. Together with the other symptoms of thoracic choriocarcinomas, there is often an effemination syndrome with gynecomastia, testicular atrophy, and a high rate of prolan B. The course is even more rapid in men than in women and does not show any regression. No effective therapeutic approach to choriocarcinoma has been found, as many histogenic, biological, and etiological problems are still unsolved.

Examinations of Atypical Mycobacteria: Comparative Bacteriological Examinations Concerning Identification and Classification into Groups. G. Meissner. Beitr. Klin. Tuberk. 120:377-387 (No. 6) 1959 (In German) [Berlin].

Bacteriological examinations of 80 strains of atypical mycobacteria were carried out in order to identify them and to differentiate them from the known human and bovine strains of tubercle bacilli, and to classify them into 4 different groups. Drug-susceptibility tests with isoniazid, streptomycin, aminosalicylic acid, and amithiozone (Conteben) proved to be very useful in the identification of atypical mycobacteria. The atypical acid-fast bacilli are more resistant to chemotherapy than the human and bovine tubercle bacilli obtained from untreated patients. The atypical mycobacteria can also be differentiated from the human and bovine tubercle bacilli by the positive peroxidase reaction of cultures grown on a medium containing isoniazid in a concentration of from 10 to 50 mcg. per milliliter, as well as by a negative niacin test. The examination of cultures on Löwenstein-Jensen egg medium and on 5% glycerol agar at different temperatures makes it possible to classify the mycobacteria into the following 4 groups: (1) photochromogenic; (2) scotochromogenic; (3) avian and avian-like; and (4) "fast-growing," generally considered saprophytic.

BOOK REVIEWS

The Acute Radiation Syndrome: A Medical Report on the Y-12 Accident, June 16, 1958. Compiled by Marshall Brucer. From Medical Division, Oak Ridge Institute of Nuclear Studies, Oak Ridge, Tennessee, under contract with United States Atomic Energy Commission, Technical Information Service. Work performed under contract no. AT-40-1-Gen-33. ORINS-25, biology and medicine. Paper. $1. Various pagination, with illustrations. Office of Technical Services, Department of Commerce, Washington 25, D. C., 1959.

In a series of 13 laboratory and clinical studies made on five persons who were accidentally exposed to whole body radiation of large doses of radiation at Oak Ridge, Tenn., additional information concerning the clinical, hematological, and biochemical changes after exposure is described in detail. The five persons, each exposed to 200 to 300 rads, were hospitalized immediately. Extensive studies were begun at once and continued until the patients were discharged. Three additional persons who received doses of 70 to 20 rads were similarly studied as outpatients.

A record of the profile of residual radioactivity from the feet to the top of the head of each patient was made with a linear scanner. Recordings reflected the general distribution of radioactivity, presumably sodium-24, throughout the body. The tracings resembled the profile of the supine human body. The method permitted determination of relative amounts of remaining radioactivity and, by comparison of the tracings, permitted serial studies of the residues remaining within the body. Although the method does not yield quantitative results, the comparisons are informative. The patients followed well-recognized patterns of the postradiation syndrome, but there was some variation among the symptoms and the amounts of radiation received. For example, the patient who had the greatest exposure had the most severe symptoms and the patient who had the smallest exposure had the second most severe symptoms and hematological changes. There was also some variation in the intensity of the exposure of the intervening patients and in their clinical and laboratory examinations. The acute radiation syndrome follows a defined sequential pattern. It takes longer to develop bone marrow depression in man than in the experimental animals used in the past and also a longer time for man to recover from the bone marrow depression. One interesting sidelight was the study made on a burro experimentally exposed to a comparable amount of radiation, which yielded results similar to those observed in man.

Several biochemical studies of the effects of the acute radiation syndrome were significant. Patients treated with beta-aminoisobutyric acid (BAIBA), a newly discovered urinary acid presumed to be a product of thymine metabolism, were observed to have excretion rates that were related to the dosages received. Although further work is needed to establish the relationship, preliminary reports indicate that BAIBA may be used to measure the severity of dosage of radiation. Exposed patients showed essentially normal biochemical findings except that taurine excretion was elevated and serine was absent from the urine. The bactericidal power of serum against enteric gram-negative bacilli was not reduced in patients exposed to large amounts of whole body radiation.

The concluding paper by Brucer summarizes the clinical, hematological, and psychological effect of the acute radiation syndrome. The author has used three-dimensional drawings to illustrate plotting dose against time and severity of symptoms. This method clearly demonstrates the problems involved in the assessment of clinical and hematological findings after whole body radiation.

The book is an excellent compilation of studies of the acute radiation syndrome and should be studied by all who are interested in the field. It contains appropriate suggestions about health physics and the prevention of radiation hazards and a well-reasoned statement of the complex medical problems connected with these unfortunate accidents.

Chronic Illness in the United States. Volume III: Chronic Illness in a Rural Area. The Hunterdon Study. Reported by Ray E. Trussell, M.D., M.P.H., Chairman, School of Public Health and Administrative Medicine, Columbia University, New York, and Jack Elinson, Ph.D., Associate Professor, School of Public Health and Administrative Medicine, Columbia University. Study of prevalence of chronic illness and needs for care in rural area. Conducted by Hunterdon Medical Center, with assistance from National Opinion Research Center, and State of New Jersey Department of Health. Supported by grants from Commonwealth Fund and sponsored by Commission on Chronic Illness. Cloth. $7.50. Pp. 440. Published for Commonwealth Fund by Harvard University Press, Cambridge 38, Mass.; Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, England, 1959.

This third volume in a series of four volumes is the companion work to volume 4, which presented a survey of chronic illness in a large city. The present volume, in keeping with the high standards of the other three, presents a carefully documented assessment of chronic illness in a rural area. The region selected was Hunterdon County, a prosperous area in northern New Jersey, along the Dela-

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

ware River. This county has 26 municipalities, 14 townships, 10 boroughs, one town, and one city. Only two of these municipalities have more than 4,000 residents. The people of this region have a strong interest in community and civic affairs.

The Hunterdon study is a report by Drs. Ray E. Trussell and Jack Elinson of the School of Public Health and Administrative Medicine, Columbia University. They were ably assisted by an adequate staff. They took the classic approach of appraising the community in general and using family interviews with multiple-screening procedures for the purpose of determining the extent of long-term illnesses in this region.

This volume has 15 chapters, 5 appendixes, and an index. Experience with previous studies was rewarding since a number of important observations were made during them. The number of the various disorders which were discovered was far in excess of earlier estimates. The survey was divided into five interrelated but successive phases: the community's survey of itself, the family interview, medical verification, clinical evaluation, and multiple screening. The results represent six months of full-scale planning and pretesting, two and one-half years of intensive survey work, and two years of analysis and reporting. The close cooperation between the doctors in the community and those who were conducting the survey is evidenced by the fact that 85% of the physicians replied to questionnaires.

The appendixes include the forms used in the survey, case reports of successful recruitment of a person for clinical evaluation who had initially refused to cooperate, code numbers and diagnoses used, the outline used by the social worker, and the diagnoses made in clinical evaluation. This book should prove an inestimable help for the staff now working on the National Health Survey. It should also prove illuminating to faculties of our medical schools and, indeed, to the student body. General practitioners, public health physicians, social workers, and leaders in the broad fields of community welfare should find here an invaluable source of information that is essential for a better understanding of the challenge of long-term illness in the rural communities of the nation.

Ciba Foundation Symposium on Carcinogenesis: Mechanisms of Action. Editors for Ciba Foundation: G. E. W. Wolstenholme, O.B.E., M.A., M.B., and Maeve O'Connor, B. A. Cloth. $9.50. Pp. 336, with 48 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6, 1959.

The 29 papers presented here were given at the Ciba Foundation in 1958 just before the Seventh International Cancer Congress, which was held in London. In the first chapter, I. Hieger of London discusses the various theories of carcinogenesis, most of which are presented in [illegible] book. The relatively new theory that viruses may cause cancer is ably discussed by Jacob Furth of Boston. His theory may be summarized by the statement that we may "think of tumor-producing viruses as self-replicating nucleic acids, probably DNA" and should "distinguish sharply between two type of conceivable changes: cytogenetic and parasitic."

The immunological aspects of cancer are discussed by Green, who has been interested in this phase of research for many years. He reviews the theory that "malignant change is due to loss of factors conferring immunological identity on the cells of a tissue." It is his contention that lipoproteins are specifically involved in the immune reactions. The mechanisms of production of bladder cancer have been discussed ably by Boyland. The production of leukemia and other types of malignant tumors in mice by injection of filtrates obtained from organs of mice having leukemia, as reported first by Gross in 1951, is presented by Latarjet of Paris. One of the interesting and informative features of this volume is the discussion of the various papers. Since practically all of the authors were working in the field of carcinogenesis and were well acquainted with each other, this discussion becomes still more pertinent and valuable.

Neurology of Infancy. By Anatole Dekaban, M.D., Ph.D., Head, Section on Developmental Neurology, National Institute of Neurological Diseases and Blindness, National Institutes of Health, Bethesda, Md. Cloth. $12. Pp. 388, with 185 illustrations. Williams & Wilkins Company, 428 E. Preston St., Baltimore 2, 1959.

The author of this welcome addition to the literature of pediatric neurology states in the preface that his two main objectives in writing this book were to describe anatomic and developmental landmarks of the maturation of the central nervous system in infancy and to outline the principles of pathology, pathogenesis, and clinical manifestations of the neurological disorders of infancy, with special emphasis on the differences between such processes in the infant and the adult. The book opens with an excellent chapter on the developmental anatomy and physiology of the nervous system during the first two years of life, with concise descriptions and photographic illustrations of the gross and microscopic anatomy of the brain and spinal cord at birth and at the four subsequent six-month intervals. Good discussions are presented of the rate of myelination, the development of cytoarchitecture, the maturation of cellular components of the nervous system, the neurophysiological development of the infant, and the average rate of acquirement of motor and intellectual skills, with tables showing normal physical measurements and indexes.

The second chapter is a valuable description of methods of examining the infant neurologically; it discusses techniques not well known even among well-trained neurologists. In the remaining chapters the reader finds discussions of birth injuries, vascular disorders, infections (including meningitis, numerous varieties of encephalomyelitis, poliomyelitis, and fungus infections), dysrhaphic states, cerebral palsy, epilepsy, mental deficiency, dysgenic states, neoplastic and granulomatous formations, metabolic and endocrine disorders, neurodegenerative diseases, and the myopathies. Extensive and well-chosen references add much to the value of each chapter. Profuse illustrations portray clinical, roentgenographic, and gross and microscopic pathological features of the neurological diseases of the infant. An adequate index gives references to subject matter and to illustrations. The binding is attractive and sturdy, befitting a book designed for use in hospital or clinic.

For the most part this is an admirable work. The initial chapter on anatomic and neurophysiological maturation is an ideal introduction to a textbook of pediatric neurology. The author rightly maintains that knowledge of normal development is necessary for any evaluation of neurological abnormality in the infant but that this field is often neglected. Disease of a portion of the brain not yet functioning can scarcely be detected; for example, one cannot speak of a defect of motor or mental skills until those skills should have been acquired. The chapter on the neurological examination of the infant is so good that it is indispensable. The section on epilepsy is refreshingly sane and fortunately avoids the over-rating of the electroencephalogram so often evident. It is precisely in connection with epilepsy in the infant that the clinical and electrographic features of the disorder depend so clearly on the degree of maturation of the brain. It is surely the neurological immaturity of the cerebrum that renders the infant so susceptible to convulsions, determines so largely the type of the seizure, and probably makes the infant so responsive to such anticonvulsant drugs as the diones and unresponsive to others. It is therefore surprising that the author scarcely notes this striking exemplification of his own major thesis. The section on metabolic and endocrine disorders is notably direct and clear. No other single discussion of these numerous and complex conditions is at once so inclusive and so succinct. Other portions of the book are similarly valuable in coverage and organization, such as the chapters on vascular disorders, encephalitis, and mental deficiency and retardation of development.

One must nevertheless note that this book has certain defects. It is by no means an encyclopedia of pediatric neurology. Many topics are discussed superficially or vaguely, for example, the chemical basis of porphyria (p. 276), the processes underlying antoimmunization and erythroblastosis fetalis (p. 277), and the myotonic states, which are described clinically but without mention of the electromyogram (p. 371). It is unfortunate that treatment is often only casually indicated without details of administration, differential criteria, or dosages. For example, in connection with intracranial aneurysms it is stated that the presence of blood in the spinal fluid indicates bleeding and that "in a proportion of patients surgical exploration preceded by an arteriogram can be attempted if facilities permit," but no explanation is given of the principles of nonsurgical management or of the tremendous decisions necessary about the optimum time for angiography or the locations and types of lesions that should be made. Again, in a rather full discussion of poliomyelitis, there is no suggestion that a vaccine for prevention is available. Tetanus is apparently not mentioned, nor is neuritis except for the neuropathy of vitamin B_1 deficiency. Certainly the neuritis of diphtheria should have been described. Scurvy is also not dealt with, though hemorrhages resulting from it may occur in the subdural space, orbit, and elsewhere with serious neurological consequences. No reference is made to the convulsive states due to deprivation of vitamin B_6.

A few errors are apparent. Hutchinson's teeth in congenital syphilis appear only in the second dentition, never during infancy (p. 127); acute syphilitic meningitis is a serious and fatal disease and does not "tend to subside even if not treated" (p. 128); and the pyramidal tracts are not involved in the Werdnig-Hoffmann type of spinal muscular atrophy. Despite these flaws the book should be of value to the young pediatrician, general practitioner, and neurologists who are unfamiliar with young patients.

Biopsy Manual. By James D. Hardy, M.D., Professor and Chairman of Department of Surgery, University of Mississippi School of Medicine, Jackson, James C. Griffin, Jr., M.D., Assistant Instructor in Surgery, University of Mississippi School of Medicine, and Jorge A. Rodriguez, M.D., *Assistant Professor of Surgical Anatomy, Department of* Surgery, University of Mississippi School of Medicine. Cloth. $6.50. Pp. 150, with 54 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, England, 1959.

The authors of this volume describe indications, techniques, precautions, errors, and complications in connection with biopsies in general and for specific regions. They emphasize the importance of taking a sufficiently large piece of tissue or multiple pieces without crushing or tearing and furnishing of pertinent clinical information to the pathologist so that he can make studies necessary for proper diagnosis. They recognize the need in some cases for studies on fresh unfixed tissues to find bacteria, fungi, or even viruses. They also call attention to the importance, especially in office practice, of prompt fixation in a suitable fixative of the ordinary routine biopsy specimen, taken, as a rule, to determine the presence or absence of malignancy. Various fixatives and their formulas and uses are described. The addition of 10 Gm. of sodium bicarbonate to one gallon of 10% formalin, as suggested by the authors, is not to be recommended however. Many pathologists and surgeons will not agree with some of the recommendations for fixation of various tissues and serous fluids. In this phase of pathology, previous arrangements made between surgeons and local pathologists should be followed.

Later chapters contain ably illustrated orthodox information about obtaining material for pathological study from nearly every organ in the body. This information will be helpful to general practitioners, surgeons, and specialists in many fields Instruments used in various portions of the body are shown and described. The problem of the use of properly chosen anesthetics and management of any reactions to them is well presented. Fundamental surgical principles as well as technical details for the more skilled operator are discussed in detail. The subject of the use of excisional biopsy for diagnosis and cure of some lesions of the skin is ably handled. Chapters of interest to most readers should be those concerning skin, lymph nodes, breast, oral cavity, organs of the neck, rectum, prostate, bladder, cervix, and endometrium.

For those who wish information on preparing vaginal and cervical smears for cytological examination, a fairly comprehensive description and discussion of this subject is included. Techniques and indications for obtaining specimens of tissues in the thorax, abdomen, mediastinum, kidney, and adrenal gland are also described. Techniques for obtaining marrow by puncture or removal of a portion of bone and marrow should be of interest to the hematologist. A comprehensive bibliography is appended. This book should be useful as a guide in teaching medical students, interns, and resident staff members in hospital training and as a reference book for the practitioner who has had sufficient experience to warrant his use of the techniques described.

The Foot and Ankle: Their Injuries, Diseases, Deformities and Disabilities. By Philip Lewin, M.D., F.A.C.S., F.I.C.S., Professor of Orthopaedic Surgery, Post-graduate Medical School of Cook County Hospital, Chicago. Fourth edition. Cloth. $14. Pp. 612, with 339 illustrations, special drawings by Harold Laufman, M.D., F.A.C.S., Associate Professor of Surgery, Northwestern University Medical School, Chicago. Lea & Febiger, Washington Sq., Philadelphia 6, 1959.

This new edition of a most reliable and comprehensive textbook has been greatly improved. The carefully outlined subject matter of the previous editions has received detailed attention so that the student, resident, and surgeon may depend on it to include the most recent details to be found in the literature on the subject. Many illustrations have been added or substituted to conform to the modern concepts of cause, diagnosis, and treatment. This book adequately covers the entire subject of the foot and ankle. The author has been careful to establish anatomic, physiological, and biomechanical basic principles on disturbances of these parts. The book covers the subjects of congenital defects and deformities; disturbances of the epiphyses of the foot and ankle; affections of muscles, tendons, fascias and bursa; injuries, including sprains, strains, fractures, and dislocations; and estimations of foot and ankle disability. These subjects are discussed from the civilian and military viewpoint. The author has brought up to date the teachings on amputation, local anesthesia, skin grafting, peripheral vascular lesions of the lower extremities, anterior poliomyelitis, and cerebral palsy, and techniques of transplanting tendons and arthrodesis, and other procedures. This book can be highly recommended as a complete textbook on the foot and ankle.

Dermatologie und Venerologie einschliesslich Berufskrankheiten dermatologischer Kosmetik und Andrologie. In fünf Bänden. Herausgegeben von Prof. Dr. Dr. h.c. H. A. Gottron, Direktor der Universitäts-Hautklinik Tübingen, und em. o.ö. Prof. Dr. Dr. h.c. W. Schönfeld. **Band III, Teil 2: Krankheiten der Hautanhangsgebilde einschliesslich Akne und Rosacea.** Bearbeitet von R. Baumann et al. Mit Namen- und Sachregister für Band III, Teil 1 und 2. Cloth. 178 marks; $42.40. Subscription price 142.40 marks; $33.90. Pp.695-1401, with 317 illustrations. Georg Thieme Verlag, Herdweg 63, (14a) Stuttgart, West Germany; [Intercontinental Medical Book Corporation, 381 Fourth Ave., New York 16], 1959.

Although the title of this volume indicates that it deals with diseases of the skin appendages, including acne and rosacea, it covers a much larger territory, much of it in a masterful manner. Some of the longer chapters deal with diseases of the sudoriferous and sebaceous apparatus, hairs and nails, eruptions associated with deficiency states, metabolic and endocrine disturbances, leukemia, lymphomas, and diseases of the liver, pancreas, urogenital system, and gastrointestinal tracts. A summary of the basic histopathological, physiopathological, and biochemical features is presented in most chapters, with the etiology, clinical features, differential diagnosis, and management of the various diseases.

A successful attempt has been made to cover the literature with plentiful references to work published in European and non-European countries. As would be expected in a work of this type, few of the references are more recent than 1957. The names of the authors of pertinent work are found in the text and the detailed references are found at the end of each chapter. Perhaps too much stress is placed on fancy nomenclature such as "erythema hyperceratoticum dyspepticum supra-articulare digitorum (Csillag)." The clinical and histopathological illustrations are of superior quality. While management of the various cutaneous diseases covered in this volume is included, this book is a reference work rather than a guide for the practitioner. As such it should be highly useful for the dermatologist and nondermatologist.

QUESTIONS AND ANSWERS

DISSOLUTION OF BILIARY STONES WITH ETHER

To the Editor:—*A 70-year-old patient has had a cholecystectomy and removal of stones from the common bile duct. Two years later he had a second episode of jaundice, and after biliary calculi had been removed from the common bile duct a T-tube was put in place for irrigation of the duct. Last summer this series of events recurred and the second T-tube is still in place. Since then I have irrigated the T-tube weekly and each time have flushed out small stones. The patient suffers no discomfort except from the T-tube, which is deteriorating. I have read about the ether treatment for the dissolution of gallstones. Would this therapy be suitable for my patient?*

Sam B. McFarland, M.D., Lebanon, Tenn.

Answer.—The ether treatment (Pribram method) attains its best results in patients whose stones consist entirely or mainly of cholesterol, because the latter is soluble in ether. If the calcium content of the stone is high (as determined by roentgenogram), the ether method is of little or no help. It is better to have a catheter in the common bile duct than a T-tube, because the ether will pass through both limbs of the T-tube and cause pain and liver damage by flowing through the cephalic branch of the tube. It is helpful to administer 1/100 grain (0.6 mg.) of nitroglycerin, sublingually, at the time of etherization, for this relaxes the sphincter of Oddi and facilitates passage of small fragments of the stones. In the patient described, it might become necessary to reoperate, with performance of immediate cholangiography, if possible, and the placement of a catheter into the common bile duct for later roentgenographic study and etherization.

AUTO-UROTHERAPY

To the Editor:—*What is the efficacy of treatment, for a patient with migraine headaches, which includes injections of the patient's urine?*

Harold L. Boyer, M.D., Las Vegas, Nev.

Answer.—There is no scientific evidence which will substantiate either the rationale of this treatment or the hypothesis usually advanced by its proponents that "the antigens responsible for the headache are filtered through the glomeruli of the kidneys rather than passing from the capillaries into the tissue spaces (the usual route). By mechanically transferring the antigens to the tissue spaces by intramuscular injection of the sterile urine the allergy may be overcome."

Claims of successful treatment with auto-urotherapy can most likely be found, but it must be remembered that the patient with migraine headache often has emotional factors superimposed on the organic lesion. The use of urine as a placebo in these circumstances seems somewhat medieval in nature.

LOSS OF HAIR IN YOUNG WOMAN

To the Editor:—*A 21-year-old woman had a normal growth of hair until she was 18 years of age, at which time her hair began to fall out. Next, the hair became oily and the loss of hair increased. During the following year she became pregnant, and in the fourth month of pregnancy her hair stopped falling out, new hair began to grow, and the oiliness decreased. One month after delivery of the baby, her hair again began to fall out and became oilier. During the patient's second pregnancy, at the age of 21 years, the process of hair restoration, followed by thinning after delivery, repeated itself. The hair distribution on the rest of her body is normal and has not been affected. Her menses have been normal. Please comment on this patient's problem.* *M.D., New York.*

Answer.—The history presented by the patient is not unusual. The patient has seborrhea oleosa which is described in Behrman's chapter on seborrheic diatheses (The Scalp in Health and Disease, St. Louis, C. V. Mosby Company, 1952, pp. 220-234). The excessive amount of oily secretion bathes the hair and scalp, thus causing a glossy appearance, and, in some patients, is associated with the type of progressive loss of hair referred to as "female-patterned" alopecia. The oiliness and the loss of hair often decrease during pregnancy because of the resultant hormonal changes.

The mechanisms of these clinical observations are not specifically understood, although it is obvious that various hormonal factors are involved. In general, it has been assumed that androgenic hormones increase both sebaceous gland excretion and loss of scalp hair, while estrogenic hormones have the opposite effect. Unfortunately, such assumptions are not confirmed sufficiently to warrant specific

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

estrogen therapy, unless thorough endocrine studies indicate its value in a patient. The endocrine balance of each patient should be thoroughly studied, and therapy should be specifically related to the findings obtained. In some patients the administration of estrogens and di-iodothyronine have been beneficial. Local measures, such as use of antiseborrheic shampoos and lotions, may be of some help.

NODULES IN THE TENDO ACHILLIS

To the Editor:—*A 64-year-old dentist has painful nodules in the tendo achillis just above the ankle joint, which bother him when he walks. Results of diagnostic tests on blood and urine specimens have been negative, and a roentgenographic film showed the nodules to be soft tissue swellings without calcification. The only treatment given has been injection of hydrocortisone into the nodules, with resultant temporary relief from pain. What should be done to obtain a definite diagnosis, and what treatment can be recommended?*

F. K. Hurt, M.D., Jacksonville, Fla.

Answer.—The type of nodules described usually are of arthritic origin and are likely to occur in patients with gouty arthritis. A finding of a normal blood level of uric acid in a single, or even several, specimens does not rule out this condition. The nodules due to gout have a characteristic microscopic appearance. The only treatment for the nodules is excision, and, unless the patient is treated for his general systemic disease, the nodules are likely to appear elsewhere and may recur in or near their original site.

BREAST CANCER AND OOPHORECTOMY

To the Editor:—*Should an oophorectomy be performed as a prophylactic measure in all patients with cancer of the breast, or should it be used only for patients who have metastatic lesions?*

Paul B. Shuey, M.D., Long Island City, N. Y.

Answer.—A categorical answer is not possible because knowledge of estrogen-dependent or non-estrogen-dependent breast cancers is incomplete. There is no accurate way to determine the effect estrogen may have on a specific malignant lesion, but an estimate of estrogen dependence can be made from the histological picture of the breast tumor. A well-differentiated breast carcinoma is presumed to have estrogen dependence whereas the undifferentiated carcinoma is considered to be non-estrogen-dependent. The premenopausal patient with breast cancer should be considered a candidate for oophorectomy, which should be performed at the time of radical mastectomy. The general consensus, however, is that oophorectomy in the premenopausal patient is desirable in all cases.

Although the premenopausal patient is a candidate for oophorectomy, each patient must be appraised by the attending surgeon, with serious consideration of the total patient problem before he decides whether or not that patient should undergo this operation. Oophorectomy is not categorically indicated for all patients with metastatic breast cancer but definitely should be considered, especially if the patient is still menstruating. Regression of metastatic lesions in soft tissues compared to that in bone after oophorectomy depends on several factors. The lesions with the highest incidence of regression are those located in skin, subcutaneous tissue, and lymph nodes, while regression of metastasis in bone is less marked.

In the postmenopausal patient adrenalectomy must be considered in addition to oophorectomy, since the ovaries may still have functioning stroma. The type of soft tissue involved, the age of the patient, the other sources of estrogen, such as the adrenals, are the factors that must be considered in endocrine palliative therapy for metastatic breast cancer.

IDIOPATHIC EDEMA

To the Editor:—*A 29-year-old woman has had three normal pregnancies during which she had no excessive weight gain, albuminuria, or glucosuria. Three weeks after the termination of her second pregnancy she developed edema of both legs, more severely in the right one. A complete physical examination did not indicate any abnormalities. The edema lasted for three weeks, then disappeared spontaneously, and reappeared two years later. Edema, more severe than before, occurred about 10 days after the delivery of her third child; it was present for one month and again subsided spontaneously. No cause for the edema has been found. She has had no other signs or symptoms. Can you supply any suggestions as to the possible cause of the edema in this patient and the type of further investigative study to be done?*

R. F. DeWitt, M.D., Plymouth, N. H.

Answer.—Although there is no history of pain, tenderness in the legs, or fever, deep venous thrombosis is the most likely diagnosis. A careful examination, including the Trendelenburg test, of the patient's leg veins might disclose incompetent valves of the deep veins which result from deep venous thrombosis. Absence of this finding does not exclude the diagnosis. The exact distribution of the edema can be used to establish the location of thrombi which may be in the femoral or iliac veins or in the vena cava. Lymphatic obstruction can cause a rapid accumulation of edema fluid but such edema is not likely to subside spontaneously. Intravenous urography and barium enema examination are useful in the exclusion of lymphatic obstruction of the pelvic region. Edema due to heart or kidney disease is not a factor, since the patient has no signs or symptoms of such illnesses.

If the patient desires another child, another pregnancy would not be contraindicated. If the edema recurs, concomitant heparin and hydrochlorothiazide therapy should be given, even though there is no other evidence of venous thrombosis.

LOSS OF HEARING FROM GUN NOISE

To the Editor:—*Will the loss of hearing due to loud noises (firing of rifle and/or pistol) be temporary or permanent? Should one discontinue shooting or can ear plugs be used to prevent loss of hearing from loud noises?* *M.D., Nevada.*

Answer.—If the loss of hearing caused by firing of guns has persisted longer than 7 to 10 days, it will be permanent, but frequently it will last only a few days. Once the condition has become permanent, there is no treatment. If the loss has occurred over a short period and from firing only a few rounds of ammunition, the patient should discontinue shooting. If it has occurred over a long period (10 to 15 years), there is no reason to discontinue shooting. It is best to wear ear plugs while shooting, because they do prevent injury due to loud noises.

UNTOWARD REACTIONS TO LOCAL ANESTHETICS

To the Editor:—*Can intradermal or conjunctival tests be used to determine a patient's sensitivity to local anesthetics? If the patient does have such a sensitivity, is it possible to desensitize him?* *M.D., Alabama.*

Answer.—Although local anesthetic agents may produce an abnormal systemic reaction in a patient, it is doubtful that any anesthetics commonly used could cause true tissue sensitivity that would be prevented by graduated doses of these agents. Allergic manifestations of this nature usually depend on the presence of a protein which is involved in the antigen-antibody reaction.

Reactions to local anesthetic agents administered to the patient prior to dental repair consist of palpitation, dizziness, or fainting. These can be caused by epinephrine or other vasoconstrictors in the solution, or by emotional instability of the patient. Any local tissue swelling which may occur has been attributed to histamine release and can be prevented by administration of an antihistaminic drug. Localized tissue swelling also can be the result of increased reaction by the patient's tissue to trauma.

The future management of a patient who has had one episode of local tissue swelling and may need further dentistry would include a history of the agents used prior to the reactions and knowledge of whether or not vasopressor drugs had been included in the solutions. Since anesthetic agents of distinctly different structure and composition are available, it is possible to use one not related to the one previously administered. Although the value of skin testing is questionable, it should be performed with the agent to be used. Use of vasopressor drugs should be avoided, and it might be wise to give the patient an antihistamine prior to injection of the anesthetic. Should skin tests indicate a reaction, the local nerve block technique should be avoided and a general anesthetic, such as nitrous oxide, given.

GLUCAGON

To the Editor:—*Is the treatment of a patient with insulin hypoglycemia by intramuscular administration of crystalline glucagon (hyperglycemic-glycogenolytic factor) safe and practical? Where can glucagon be obtained? Elrick and associates wrote on this topic (Glucagon Treatment of Insulin Reactions,* New England J. Med. 258:*476 [March 6] 1958).*

H. M. Jardine, M.D., West Branch, Mich.

Answer.—Management of insulin hypoglycemia by glucagon is entirely safe. The levels of blood sugar obtained from the blood of a patient treated with glucagon are in the normal range or somewhat higher but never excessive. Mild or moderately severe insulin reactions can and should be treated by the patient through ingestion of sweetened food or drink. Severe reactions usually are managed by his family or a physician. It is doubtful that an ordinary family would have a member with sufficient knowledge of technique to give the injection of glucagon. If given by the physician, it does provide a safe and effective means of treatment, and, since intravenous injection is not necessary, it has an advantage over the intravenous administration of dextrose. Glucagon is not commercially available.

ARGYRIA FROM SILVER NITRATE CAUTERIZATION

To the Editor:—*Could argyria result from the repeated application of silver nitrate in cauterization of the edges of the healing tissue of a patient on whom a pilonidal cyst excision has been performed? The applications are done 6 to 10 times weekly.*

Lucian J. Fronduti, M.D., New Kensington, Pa.

Answer.—There appears to be no record of argyria occurring in a patient from the use of silver nitrate on a pilonidal surface wound. The granulation tissue should be cut away so that a lesser amount of silver nitrate needs to be used, and the physician should be aware of the early symptoms of argyria. Argyria is not likely to be caused by the technique described, but there is a considerable variation in patient tolerance to the heavy metals.

TUBERCULIN SKIN TEST SOLUTION

To THE EDITOR:—*Is there a tuberculin skin test which is packaged in amounts of one to three tests, or is there a package providing solutions of old tuberculin or purified protein derivative (PPD) which, after mixing, will remain stable for more than a few days? The average physician in general practice may perform only a few tuberculin skin tests per month, and a large part of the materials contained in available packages must be discarded.* *M.D., Maryland.*

ANSWER.—A check on the availability of a one-test vial of tuberculin (PPD) did not disclose any company that markets this product in this size. The customary sizes are 10-test and 100-test packages. To prevent wastage of a portion of the 10-test vial, the physician should schedule a sufficient number of patients for tuberculin testing within a three-day or four-day period, thus making more complete use of each vial.

PREGNANCY AND QUININE TONIC WATER

To THE EDITOR:—*Several patients have inquired about the drinking of quinine water during pregnancy. How much quinine would have to be consumed by a pregnant woman to be toxic to the fetus?* *M.D., Illinois.*

ANSWER.—Deafness in a newborn child has been attributed to administration of therapeutic quantities of quinine to the mother during pregnancy, and for this reason use of the drug has been abandoned for the induction of labor. Apparently no toxic effects have occurred in the fetus from maternal doses below 600 mg. daily. The quantity of quinine hydrochloride in a 10-oz. bottle of "tonic water" is about 25 mg. An expectant mother would have to consume more than 20 bottles of quinine water daily before toxicity might be seriously considered.

PIGMENTED SPOTS ON THE FACE

To THE EDITOR:—*A 34-year-old woman has numerous so-called "liver spots" on her forehead and both cheeks. She is married to an Air Force officer and has lived in various regions of the United States and in foreign countries. She has no children and is not pregnant. What type of dermatosis is this?* *M.D., Alabama.*

ANSWER.—Liver spots usually are described as circumscribed, irregular areas of macular pigmentation on the exposed areas of the face; they occur frequently in women. Other names for this pigmentation are melasma and chloasma. The pathogenesis of these lesions is unknown. In northern latitudes the pigmentation frequently becomes almost imperceptible during the winter months and is, therefore, not a new melanin formation but a seasonal darkening of pigment related to solar exposure. This darkening of pigment can be prevented by application of a chemical sun filter which blocks the long-wave ultraviolet rays of sunlight.

PSEUDOCYST OF THE PANCREAS

To THE EDITOR:—*A 28-year-old man, injured in an automobile accident, received an injury which lacerated the superior portion of the pancreas but did not involve the major duct. The capsule of the pancreas was repaired, and a drain was placed through the abdominal wall which extended down to the injured site. Copious drainage occurred on the 3rd but stopped by the 10th postoperative day. The patient has had no pancreatic symptoms since recovery from his injuries. What is the possibility that a pancreatic pseudocyst might develop?*

M.D., South Carolina.

ANSWER.—Assuming that results of all the usual tests for pancreatic dysfunction and of other examinations of this patient are normal, he may be considered cured. The published records of patients with pancreatic lacerations who have not developed pseudocysts are inadequate for estimation of the incidence of cyst formation. From the reports of pseudocysts occurring in patients with a history of injury one might set the incidence at about 2%.

NEUROFIBROMATOSIS AND CATARACTS

To THE EDITOR:—*A woman has neurofibromatosis, with lesions located everywhere on her body. She also has a cataract of the right eye, degeneration of the retina of the left eye, and myopic vision (20/200). Several ophthalmologists have hesitated to remove the cataract because partial degeneration of the retina in the right eye has occurred, so that she might not be benefited by this operation. The patient's present treatment includes injections of liver, vitamin* B_{12}*, and vitamin A. Her loss of vision has increased only slightly during the past two years. Are there any other medicaments which would improve either the retinal condition or the neurofibromatosis? Do these conditions usually occur concurrently?*

E. Milton Staub, M.D., Westfield, N. J.

ANSWER.—Neurofibromatosis may involve any structure of the eye, but this patient's cataract appears to be unrelated to the disease. The occurrence of retinal degeneration, if not associated with tumor, is also incidental. There are no medical remedies which are of benefit to the patient with either of these conditions.

Administration Considers New Health Bill . .
Water Pollution Bill . .
Health Budget Rapped . .

SENATE SUBCOMMITTEE RECOMMENDS FORAND-TYPE PROGRAM

Arthur S. Flemming, Secretary of Health, Education, and Welfare, told a news conference he "hopes" to send to Congress within 60 days a measure aimed at meeting some of the health needs of elderly persons.

He declared his department is working on three approaches to provide catastrophic health insurance for the aged, through (1) the social security system; (2) Public Assistance Program grants; or (3) some form of supplementing voluntary private insurance. He emphasized that no conclusion had been reached yet within the administration on which type of program to support. His remarks followed a similar statement made by President Eisenhower at his weekly meeting with reporters.

In another important development here, the special Senate labor subcommittee on aging issued its long-awaited report, which endorsed a sweeping program of health care for the aged through the social security system. The Democratic majority of the subcommittee, headed by Sen. Pat McNamara (D. Mich.), concluded that "The no. 1 problem of America's senior citizens is how to meet the cost of health care at a time when income is lowest and potential or actual disability at its highest."

In reply, Dr. Louis M. Orr, President of the American Medical Association, declared that the subcommittee was "politically inspired." He pointed out that at seven subcommittee hearings throughout the country last fall "observers heard little support expressed by the older citizens who attended the hearings for government medicine financed by additional taxes and administered through social security."

The two Republican members of the subcommittee, Senate GOP Leader Everett M. Dirksen (Ill.) and Sen. Barry Goldwater (Ariz.), also took issue with the Democrats' recommendations. In a dissenting report, they said "It is possible for elderly people to secure private insurance to provide hospitalization and surgical benefits without any intervention by public authorities."

The two senators pointed out that the broad programs proposed by the Democrats would add billions of dollars to the cost of the federal government and thereby promote inflation, which is one of the major problems of old persons living on fixed incomes. "The problems of older Americans are basically no different from those of other citizens," the minority report said. "Their principal concern is to see the value of their savings protected by sound monetary and fiscal policies on the part of the federal government."

In addition to a Forand-type health recommendation, the subcommittee called for a hike in cash benefits for social security beneficiaries; federal subsidies for nursing homes "which meet the minimum standards for medical and restorative services"; establishment of a U. S. Office of the Aging; a 100-million-dollar annual program of housing for the elderly; and elimination of job discrimination against older persons.

Protesting the scope of the recommendations, senators Dirksen and Goldwater said they would "add to the tax burdens of everyone, raise prices, and ultimately depreciate the purchasing power of the savings of those who are no longer able to work."

"As with so many other studies, the majority's report raises false hopes that the federal government will be able to solve problems which are not susceptible to solutions by congressional enactments," said the Republicans.

In addition to Senator McNamara, the other Democratic members of the subcommittee were senators John Kennedy (Mass.), Jennings Randolph (W. Va.), and Joseph Clark (Pa.). Senator Kennedy, leading candidate for the Democratic presidential nomination, has introduced a bill that would be broader in most respects than the controversial Forand proposal.

HEW Secretary Flemming at his news conference said he wanted to "underline that the position of the administration still is in opposition to the Forand bill" that would finance partial health care for the aged through higher Social Security taxes. He gave a flat "no" in reply to a question whether the administration had reached a conclusion that the only way to deal with the problem is through the social security system. Vice-president Richard Nixon, said Flemming, was "very obviously participating" in administration discussions on the matter.

The American people, as well as the administration, he said, have "deep-seated concern" about the problem of catastrophic illnesses of the aged. He said he doubted that voluntary insurance, alone, regardless of its progress in that field, will ever be able to come up with a complete solution.

Meanwhile, the House Ways and Means Committee was scheduled to start sessions in late March or April on various proposals to change the social security laws that might include health care meas-

ures. What action, if any, the Committee takes will be of extreme importance, since it must originate all social security legislation.

WATER POLLUTION CONTROL BILL APPROVED

The House approved legislation to allow a 90-million-dollar annual program of federal grants to help localities build sewage disposal plants and take other steps to combat water pollution. The measure went far beyond the administration's recommendation that the program be limited to federal spending of 20 million dollars a year, with the communities shouldering more of the burden.

Under the bill, passed by voice vote, individual projects could receive up to $450,000 of federal money, compared with the present limit of $250,000

The measure cleared by the House was a compromise between a broader House bill and a more limited Senate measure acted on last year.

The federal government was armed by Congress with stiff powers a few years ago to order localities to clean up pollution on waterways involving interstate commerce, and the Department of Health, Education, and Welfare has already handed down several decisions compelling municipalities to move against pollution.

LAWMAKER CRITICIZES HEALTH BUDGET CUTS

Sen. Lister Hill (D., Ala.), chairman of the Senate appropriations subcommittee on health, promised to try to restore the budget reductions sought in some programs by the administration. He especially criticized the 60-million-dollar reduction sought in the Hill-Burton program of aid for hospital construction, declaring that "President Eisenhower persists in proposing crippling budgets for this vital program in the face of overwhelming evidence that all hospital construction is insufficient to replace the hospital beds lost through obsolescence and those needed to meet the population increases."

Although some health programs were decreased in the budget, the over-all spending in this field by the government next fiscal year would be 100 million dollars more than this year under the President's budget.

MISCELLANY

The U. S. Public Health Service said heart disease, strokes, cancer, and accidents accounted for 71% of all deaths in 1958. Recorded were 1,647,886 deaths that year, a rate of 9.5 per 1,000 population, compared with 9.6 in 1957. The 1958 toll included 637,246 deaths from heart disease, 190,758 from strokes and other vascular lesions, 254,426 from cancer, 36,981 deaths from automobile accidents, and 53,523 from other kinds of accidents.

PHS Surgeon General Leroy E. Burney has invited a delegation of 13 Russian scientists to this country in May for joint scientific meetings in the fields of cancer and heart disease. Dr. Burney also proposed that missions of scientists from the United States to the Soviet Union begin next October with a delegation in the field of maternal and child care.

President Eisenhower asked Congress for an extra $332,000 this year for the Food and Drug Administration to buy equipment for an expanded study of radioactivity in food.

Rep. John Fogarty (D., R. I.,), Chairman of a House appropriations subcommittee on health expenditures, introduced a bill for a 2-million-dollar annual program of scholarships for medical students. Eight thousand scholarships of up to $2,500 would be provided under the proposed 10-year program.

In a letter to Chief Justice Robert G. Simmons of the Supreme Court of Nebraska, who has suffered a heart attack, President Eisenhower had this to say: "From my own experience with a coronary, I bid you be of good cheer awaiting complete recovery. As one who had a similar experience, I can only suggest that you faithfully follow the doctor's orders, tedious as they may make the next weeks or months; but I am certain that you will without too much delay be able to resume your normal routine."

Many drug addicts are switching to cough medicines as a cheap and easily obtainable substitute for narcotics, Narcotics Commissioner Harry J. Anslinger reported. The cough syrups contain dihydrocodeinone, an opium derivative, and can be purchased across the counter at drug stores, he said.

The Federal Trade Commission said the nation's cigarette manufacturers have decided to end health claims in cigarette advertising, a move labeled as "a landmark example of industry-government cooperation in solving a pressing problem" by FTC Chairman Earl W. Kintner.

The Air Line Pilots Association brought suit in federal district court in New York seeking a temporary injunction against a Federal Aviation Agency decision to require retirement of commercial air line pilots at the age of 60 years.

The Agriculture Department ordered meat inspectors to bear down on enforcement of a regulation aimed at keeping residues of stilbestrol out of meat. The Department and the Food and Drug Administration had received complaints about violations of the rule which calls for a time interval before slaughter after the animals have been fed grain containing stilbestrol, a product that has caused cancer when fed in large quantities to test animals.

The State Department set up an interdepartmental committee on international health policy, headed by HEW Secretary Arthur S. Flemming. The committee "will function as a regular mechanism for advising the Secretary of State as to objectives, establishing long-range goals, and planning programs in the field of international health," said Flemming.

The National Institutes of Health awarded 20 grants, totaling $733,143, to support the training of research scientists in basic medical and health-related sciences. These awards, part of an NIH effort to stimulate more research training in the scientific fields basic to medicine and public health, were made to 20 institutions and universities in 16 states to provide support for the training of graduate students and postdoctoral trainees in a number of basic sciences, including embryology and development, biochemistry, physiology, microbiology, medical genetics, anatomic sciences, pharmacology, basic multi-disciplinary studies, and cell biology.

CURRENT STATUS OF ANTI-INFECTIVE THERAPY IN UROLOGY

Russell D. Herrold, M.D.
and
Nick Karabatsos, M.S., Chicago

In treating acute infections of the urinary tract, a sulfonamide drug is recommended as the first choice; if the program here outlined fails, the reason is likely to be either specific bacterial resistance or the presence of structural abnormalities. In treating chronic infections broad-spectrum antibiotics are suggested. The authors review previously published observations on 75 patients treated with kanamycin. The original organism was eradicated in about 60% of this group, but other organisms emerged after or even before the treatment was ended in about 30%. The experience of the authors indicated that underlying urologic abnormalities should be searched for, that sensitivity tests are of value in choosing the antibiotic best suited to the infecting organism, and that the possible development of resistance to the antibiotic on the part of the organism must be kept in mind.

ACUTE uncomplicated infections of the urinary tract are usually caused by bacilli. We believe that the drug of first choice is a sulfonamide, if the patient is not sensitive. It should be given in maximum dosage for at least five days and in lower dosage for an additional five days. If this therapeutic regimen fails to cure the infection, a complete urologic examination is indicated. Occasionally the lack of response is due to bacterial resistance; this is usually indicated by no subjective or objective improvement occurring in the first 48 hours of therapy. The chief current problem is the management of chronic infections without associated uropathy or with nonremediable uropathy.

In urinary infections the infecting organisms can be identified most accurately by cultures, since in this way the genus can be identified and sensitivity tests done, if indicated. If cultures are not available, gram staining of the urinary sediment, which will establish whether the infection is bacillary, "coccic," or mixed, should be done. A wet cover slip preparation is a simple method of evaluating the degree of pyuria and hematuria. Also, bacilli may frequently be identified microscopically under the high-power field, especially in samples from patients with acute infections.

The results of the disk method of sensitivity testing are more likely to correlate in vitro and in vivo if the primary inoculations are made from the patient's urine or prostatic secretion. There is usually enough growth so that it is seldom necessary to make subcultures into broth before making sensitivity tests. We believe that sensitivity readings are

---

Read before the Section on Urology at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 10, 1959.

most important when the zones of inhibition of growth show completely resistant or highly sensitive reactions to the drug. Intermediate readings between these two areas are of some importance only when two drugs are to be given in combination.

Our observations on the newest broad-spectrum antibiotic, kanamycin (Kantrex), are based on the treatment of 75 patients,[1] predominantly adult, with chronic urinary tract infections. These patients had pretreatment cultures, and adequate follow-up studies were made in all but 11 cases. All patients had had a complete urologic examination prior to therapy. Kanamycin should not be given to patients with infections due to enterococci such as Streptococcus faecalis. Frequently such organisms could be isolated during therapy or immediately thereafter. Not more than a 10% rate of cure was obtained in patients with Pseudomonas infections. There was a low rate of cure in patients with infections caused by Proteus mirabilis, which has been found [2] to be the commonest species of Proteus. Less than 20% of infections due to these three pathogens were eradicated. The best results were obtained in patients with infections caused by Escherichia coli, Aerobacter aerogenes, Paracolobactrum, intermediate coliform bacteria, Klebsiella, and staphylococci, although this last organism is usually found mixed with one of the gram-negative bacilli.

The original organism was eradicated in about 60% of these patients but there was emergence of another genus in about one-third, either during or a short time after completion of therapy. After trying various dosage schedules we established as a routine 0.5 Gm. of kanamycin every 12 hours for six days, although 1 Gm. every 12 hours is indicated in a patient with suspected or proved bacteremia. The spectrum of kanamycin is identical with that of neomycin but with less nephrotoxicity and ototoxicity, although the incidence of the latter is high when the drug is used for a long period of time, such as for tuberculosis, and there is an increased danger when 2 to 3 Gm. is given daily in short-term courses.

Resistance is said to develop more slowly to kanamycin than to other broad-spectrum antibiotics, but undoubtedly it will be a factor in the future. It has already been demonstrated that resistance develops quite readily in tubercle bacilli in patients who are subjected to treatment with the drug for long periods. We have noted frequently, in patients with infections caused by gram-negative bacteria which were not cleared up by kanamycin, that there has been an increased resistance in vitro even though the period of administration was relatively short.

Factors Influencing Therapy

The clinical types of patients selected for long-term therapy were chiefly those with chronic recurrent urinary tract infections without associated uropathy and some patients with neurogenic bladders. Our results chiefly concerned observations on 34 adults and 4 children to whom cycloserine (Seromycin) [3] was administered for from six months to three years and in whom it has proved to be quite satisfactory. There were comparatively few side-reactions with the amount of drug needed to control these infections. In some instances cultures remained positive during the administration of cycloserine but the patients usually remained asymptomatic and without pyuria. The most common organisms to persist were enterococci and Proteus mirabilis, but these bacteria were in small numbers and did not cause significant pyuria. The original inoculum frequently showed no growth on solid medium but was obtained only after the urine was incubated overnight.

Many of these patients undoubtedly had chronic pyelonephritis, diagnosis of which is frequently difficult to make.

Martin and co-workers,[4] in a recent excellent review of infections in the urinary tract, stated that renal biopsy revealed that the proportion of normal biopsy specimens decreased with the duration of infection; in only 10% of patients with chronic infection did biopsy reveal normal tissue. Yet those patients who are not treated may be subjected to progressive damage of the kidneys. It would be logical to assume that antibacterial therapy may offset this damage in many instances.

Another medicament, nitrofurantoin (Furadantin), has given encouraging results in a few adult patients to whom it was given in a total dosage of 3 mg. per kilogram of body weight per 24 hours in divided doses three or four times daily. Marshall and Johnson [5] reported successful results with prolonged administration of nitrofurantoin in chronic infections in children, as have Lippman and his co-workers [6] and Norfleet [7] in adults.

Intermittent therapy is indicated chiefly in those patients with chronic urinary infections associated with demonstrable uropathy and chronic pyuria, especially if there are frequent episodes of clinical exacerbation. A simple and often reliable method of evaluating therapy is the gross appearance of the urine supplemented by microscopic examination. Failure of the urine to clear within two or three days of therapy is an indication either of wrong choice of drug or of some underlying pathological factor. The sulfonamides are quite satisfactory for this purpose if there is favorable and tolerable response to their administration. Some urologists have advocated treatment one week of each month and others administration every other week. Usually this type of therapy requires full dosage during the period of treatment. Recently we have had some encouraging results in patients to whom sulfonamides were given every other day or every third day, depending on the duration of the favorable response after discontinuance of therapy with the drug. Methenamine mandelate is another drug of value for interrupted administration to a patient in whom the response is favorable.

There are certain types of infections in which therapy is indicated only during clinical exacerbation. Patients with such infections have chronic pyuria with little or no response during treatment. Common examples of these infections are nonremediable calculous disease of the urinary tract, infections after transureteral resection for carcinoma of the prostate, noncorrectible anomalies, and some small-caliber strictures.

Antimicrobial therapy appears to be of value in patients with chronic uncomplicated nonspecific prostatitis when the infecting organism is a known pathogen, such as Staphylococcus aureus or any of the gram-negative bacilli. Here it is of value to do sensitivity tests for selection of the best drug to be used. Acute uncomplicated prostatitis is comparatively rare, with Esch. coli the most common infecting organism, and it generally responds to sulfonamide therapy in adequate dosage. If the chronic prostatitis is secondary to associated disease, corrective surgery should be done, if possible. Otherwise, treatment should be limited to control of infection during clinical exacerbation.

Drugs in Combination

The best documented reason for the use of two agents is an infection caused by both bacillary and "coccic" organisms; what may be the best drug for one may not be the best for the other. These infections often have proved resistant to cure and, if they are chronic, there is ample time for sensitivity tests to aid in the selection of two or more medicaments.

There is apparent reduction of side-reactions to either of two drugs when they are given in smaller dosage. For instance, when novobiocin is administered in a dose of 1 Gm. per day for longer than six days there is a high incidence of dermatological manifestations, but when 0.5 Gm. is given in combination with another anti-infective drug there is a decreased incidence of side-reactions. Also, when oleandomycin is combined with a sulfonamide, each in one-half of the maximum dosage, there appears to be better tolerance to both drugs in most patients.

Synergism or potentiation has been proved in connection with the administration of penicillin and streptomycin for streptococci, notably enterococci. Also, there seems to be increased efficacy when streptomycin and chloramphenicol are administered in combination for Proteus infections. Streptomycin given in combination with tetracycline or terramycin often produces successful results in Pseudomonas infections when either one alone fails to cure. Any of these combinations presupposes that the infecting organism is sensitive or at least partially sensitive to both medicaments. We have noted frequently that when Pseudomonas has been resistant to tetracycline in vitro, it will be sensitive or partially so to terramycin.

A common example of a means of delaying or preventing the emergence of resistant organisms is the use of PAS (para-aminosalicylic acid) in combination with streptomycin and isoniazid; generally such a combination is more effective than either drug alone. We have had encouraging results in a few patients with tuberculosis of the urinary tract to whom cycloserine, 250 mg. twice daily, was given in combination with isoniazid, 150 mg. twice daily. One patient with unilateral renal tuberculosis of long duration has had negative cultures, which produced no infection in guinea pigs for nearly two years after the discontinuance of the combined therapy. Cultures from a few others have produced a negative reaction in guinea pigs but either these patients are still on combined therapy or medication has been discontinued too recently to be certain that there might not be a reversion to positive reaction later. The combination of cycloserine and biomycin has recently been reported by Ståhle[8] to be of great value in the treatment of pulmonary tuberculosis. Epstein and co-workers[9] reported that the neurotoxicity of cycloserine was reduced markedly when pyridoxine (300 mg. per day) was given in connection with cycloserine, even though 2 Gm. daily of the latter drug was given for periods of one year or more. Lattimer[10] stated that pyridoxine, 50 mg. twice daily, must be given to patients receiving isoniazid.

OXALATE URINARY TRACT STONES

Jack Hughes, M.D., William M. Coppridge, M.D.,† Louis C. Roberts, M.D.
and
Virgil I. Mann, Ph.D., Durham, N. C.

Urinary calculi were found in 4,500 hospital patients during a period of thirty-five years. Studies were made on 2,693 such stones either recovered clinically or removed at autopsy. The stones were found oftener in men than in women and oftener in the ureter than in the kidney. They were analyzed by petrographic crystallography. Calcium oxalate was the major mineral component of most of the stones encountered. Oxalate stones occurred more frequently in men and phosphate stones more frequently in women. About 20% of the oxalate stones were readily identifiable as primary, in the sense of having formed on a renal papilla, for they bore a definite indentation as if molded over a papilla and had a rough depression marking the point of attachment. The rate of 25 urinary stones per 1,000 patients discharged from this hospital was more than three times the estimated national average but is believed to be representative of the southeastern part of the country, which includes North Carolina.

The southeastern United States is one of the principal "urinary stone areas" of the world,[1] and during the period 1922-1957 we encountered approximately 5,400 urinary tract stones in 4,500 native-born patients. The current rate in Watts Hospital of 25 urinary stones per 1,000 discharges is more than three times the estimated national average.[1] A group of the stones recovered clinically and the primary oxalate stones found in a series of autopsies on adults were studied by some of the techniques currently available. Observations based on the results of these studies and a discussion of some of the current views on oxalate stone formation are presented.

The distribution of 2,693 stones on the basis of sex and anatomic locations is as follows: in the ureters, 1,400 in male and 643 in female patients, for a total of 2,043; in the kidneys, 321 in male and 329 in female patients, for a total of 650. A preponderance of ureteral stones with greater incidence in the male is evident.

The distribution of 287 unselected stones on the basis of sex of patient and major mineral content is shown in table 1. The factor of anatomic location is not considered, since deletion does not alter the results significantly. All stones were analyzed by petrographic crystallography and a quantitative estimate was made of mineral content. The monohydrate and dihydrate calcium oxalate stones are listed under oxalate; the apatites and magnesium ammonium phosphate are grouped under phosphates. Most of the oxalate stones contained more than 90% of one or both oxalates and all so classified contained more than 75%. Eight mixed oxalate-phosphate stones containing less than 75% oxalates were included in the phosphates group.

It is evident from the results in table 1 that calcium oxalate is the major mineral component of most of the stones encountered and that oxalate stones occur more frequently in male and phosphate in female patients.

The trademark of the stone belt is the primary oxalate stone (fig. 1 and 2). This term is used to describe those stones composed almost entirely of oxalate (usually monohydrate) which form on a renal papilla, usually in acid urine, in the absence of infection. When such a stone becomes detached there is a definite indentation where the stone has grown, as if it were molded over the papilla. A small, shallow, rough depression near the center of the indentation is often seen and represents the point of attachment (origin). About 20% of the oxalate stones were readily identifiable as being primary. However, this percentage does not represent the true incidence, since a primary stone often serves as a nidus for the formation of larger oxalate, phosphate, and even uric acid stones.

At least one primary oxalate stone was found in 13 of 126 autopsies done on native-born adults (table 2). The ages of the 13 ranged from 33 to 84 years.

The higher incidence of oxalate stones in men is again demonstrated in this small series. Further studies are being carried out on this type of primary stone in an effort to learn more about the mechanism of formation.

The phosphate content of "pure" primary oxalate stones was investigated. Ten primary stones measuring up to about 0.5 cm. in the largest diameter were analyzed by petrographic crystallography and x-ray diffraction; no phosphate was found. However, quantitative chemical analysis done on five of the same stones revealed a phosphate content of from 0.74 to 5.0% of dry weight. Whether this small amount represents phosphate "absorbed" from the urine in which the stone has been bathed or is a necessary part of oxalate crystallization has not been determined.

---

†Dr. Coppridge died Aug. 28, 1959.

Read before the Section on Urology at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 12, 1959.

TABLE 1.—*Mineral Content of 287 Stones Found in Unselected Patients*

	Oxalate	Phosphate	Uric Acid	Total
Male	169	20	3	192
Female	52	41	2	95
Total	221	61	5	287
%	77	21.2	1.8	100

The incidence of hyperparathyroidism in our patients with stones was less than 0.5% and therefore should not alter significantly any of the statistics presented.

Comment

The mechanism of the formation of oxalate as well as other primary and secondary urinary stones has been studied extensively. Randall[2] found that primary stones form on a renal papilla on a small subepithelial calcium plaque which has lost its thin epithelial covering or on a nidus of inspissated calcium salts in a papillary tubule. Vermooten[3] presented evidence to show that calcium salt deposition takes place in any of the collagen fibers in the renal papilla—interstitial connective tissue, basement membrane of the collecting tubules, and the circular fibers surrounding the small blood vessels. Any of these deposits may ulcerate through and lead to stone formation.

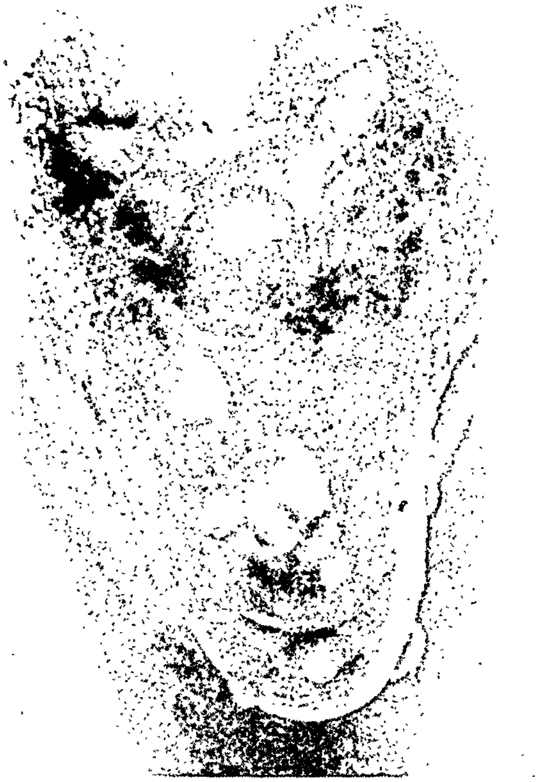

Fig. 1.—Primary oxalate stone, 1.0 cm. in largest diameter, showing typical indentation (×3).

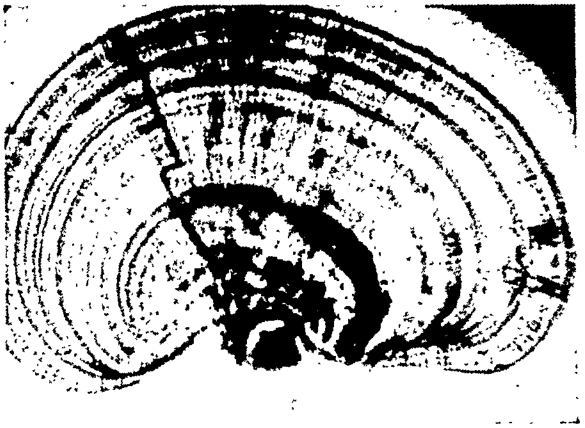

Fig. 2.—Primary oxalate stone, 3 mm. in diameter, embedded in plastic and ground to thickness of about 100 μ (×48).

In 1954 Howard[4] pointed out that a "ground substance" with staining properties similar to bone matrix had been found in some urinary stones. He suggested that since the properties of matrix apparently govern the initiation and orientation of the crystal structure of bone perhaps the matrix of at least some of the urinary stones might serve the same purpose. After extensive studies of stone matrix Boyce and King[5] concluded that the "presence of a crystallizable matrix is thus the essential phase in concrement formation." They consider matrix to be the determinant of crystal position, crystal composition, and gross stone structure and possibly a factor in the recrystallization of some stones.

It has been well established that hyperoxaluria is not a factor in the formation of most oxalate stones; the exceptions are in those patients with primary oxalosis and possibly in certain patients with sarcoidosis.[6]

TABLE 2.—*Oxalate Stones Found in Adults at Autopsy*

	No.	Primary Stones	%
Men	68	11	16.3
Women	58	2	3.5
Total	126	13	10.3

It has been proposed by many investigators[7] that all oxalate in urinary stones is first deposited as the more soluble dihydrate; when a molecule of water is lost the mineral becomes monohydrate. We have found nothing clinically to support such a thesis. Crystals of the two types are seen frequently in close approximation during the course of petrographic analysis, and the margins are always distinct. There are instances of geological formation in which a crystal structure is changed by a loss or gain of one or more molecules of water, but in such instances definite stages of transition can be demonstrated. We believe that the two types of oxalate encountered in urinary stones develop independently under different physiochemical conditions.

The greater incidence of oxalate stones in male and phosphate stones in female patients encountered in the study needs to be explained. Possibly the reason is related to hormonal activity or a sex-linked genetic factor. However, two simple explanations are worthy of consideration. (1) Male and female subjects probably have the same defect causing oxalate stone formation; the activities of the male subject at both work and play make him more readily affected by such environmental factors as heat, humidity, and stress. (2) The higher incidence of phosphate stones may be related to the higher incidence of urinary infections in female subjects.

Certain factors such as diet, infection, urinary pH, hydration, and levels of urinary calcium are known to exert some influence on stone formation, but the basic abnormality causing matrix to be formed and the particular physiochemical environment determining which mineral is to be deposited in or on the matrix remains unknown.

Summary

The southeastern United States is one of the principal "urinary stone areas" of the world, and the major mineral component of most of the stones is calcium oxalate. Oxalate stones occur more frequently in male than in female subjects. Certain factors are known to exert some influence on stone formation, but the basic cause (or causes) remains unknown.

PERIODONTAL DISEASE AND DIABETES IN YOUNG ADULTS

Capt. Ralph C. Williams Jr. (MC)
and
Major Charles J. Mahan (DC), U. S. A. F.

The observation that chronic infection predisposes to difficulty in regulation of diabetes is a concept which has been stressed by numerous authors.[1] Infection and inflammatory reactions may increase insulin requirements in a previously stable diabetic patient.[2] Much attention has been devoted in the past toward control of indolent urinary tract infections [1c] or skin infections [3] among patients with diabetes; however, relatively scanty regard has been directed at systematic eradication of chronic periodontal disease among diabetics.

Purpose of Study

Recently we have been impressed by the striking frequency with which the relatively young diabetic patients seen in a military practice manifest extensive periodontal disease which heretofore had been undiagnosed and untreated. This is, in fact, an observation to which numerous references have been made since 1899, when Grunert [4] stressed the association of far-advanced pyorrhea with diabetes mellitus. In 1928, Williams [2b] described a group of oral conditions which he termed diabetic periodontoclasia. His observations among 58 diabetic pa-

tients suggested that gingival and periodontal disease among this group constituted a distinct clinical entity. Later, Hirschfeld[5] described acute gingival abscesses and pedunculated marginal gingiva as being conditions intimately associated with diabetes mellitus. In 1938, Rudy and Cohen[6] described oral pathology among a group of 403 patients with diabetes. These authors noted a high incidence of diffuse alveolar atrophy among the younger patients and considered the periodontal symptoms as one of the manifestations of diabetes—in the same category as pruritis vulvae or transient visual disturbances. However, Glickman[7] in 1946 noted no changes in the gingival tissue or the periodontal membrane of experimental animals with alloxan-induced diabetes, although demineralization of the alveolar process was evident. Other authors[8] support the view that manifestations of periodontal disease seen in diabetics are not specific disease entities but are the results of local irritation in the presence of decreased systemic resistance.

Methods and Results of Periodontal Treatment in Nine Young Adult Diabetics

* Teeth are numbered consecutively, beginning with maxillary right third molar through maxillary left third molar as 1 through 16, and beginning with mandibular left third molar through mandibular right third molar as 17 through 32.

With the present multipurpose insulins and antibiotic support, it has become possible to treat periodontal pathology on an inpatient status, with use of surgical procedures where indicated.[9] It is the purpose of this study to describe systematic therapy of periodontal disease among a group of diabetic patients and to study the effects of these procedures on the patient's insulin requirements, diabetic control, and periodontal health.

Materials and Methods

A group of nine patients was selected from the diabetics routinely admitted or referred to the U. S. A. F. Hospital. Patients were chosen for study after control of diabetes had been accomplished by standard methods of diet and administration of insulin or orally given hypoglycemic agents. All patients manifested gross evidence of periodontal disease on initial physical examination and were referred to the periodontist for examination, diagnosis, and planning of their treatment. After stabilization of insulin requirement and diabetic program, appropriate periodontal treatment and oral surgical procedures were carried out under local anesthesia as one procedure. Exposed gingival margins subsequently were protected by periodontal surgical dressings, until healing had progressed. When gingival surgery was indicated, no limitation was placed on the amount of tissue treated at one operation. If indicated, total gingivectomy was performed in addition to necessary extractions. In fact, experience indicated that treatment of dental pathology at one fell stroke proved advantageous in selected cases. Antibiotic therapy, with use of 300,000 units of procaine penicillin G and 0.5 Gm. of streptomycin given intramuscularly twice a day was maintained for an average of 10 days in each patient subjected to treatment. Diabetic diets were continued during convalescent periods, with appropriate use of liquid and semisolid foods until gingival healing allowed return to normal foods, usually after 10 days. Each patient was followed up closely both preoperatively and postoperatively by the internist. Preoperative and postoperative therapy was coordinated between the periodontist and the internist, and close interdepartmental liaison was maintained for all patients treated. Insulin requirements and the state of diabetes were studied for a minimum of three months in each patient subjected to treatment.

Results

Seven of the nine patients with diabetes and periodontal disease who underwent elective periodontal therapy showed significant subsequent reduction in insulin requirement. The average reduction in insulin dosage was 30 units of isophane (U-40, NPH) insulin, with a range of 10 to 55 units. One patient showed no change in her insulin requirement, despite extraction of four nonvital teeth and extensive periodontal therapy. One patient with mild diabetes which originally had been controlled by diet alone later required oral administration of hypoglycemic agents for diabetic regulation. This was attributed to improvement in his eating habits after alleviation of pain in his gums. Diets and caloric intakes in all other patients were not changed significantly during the course of the study. The results are summarized in the table.

Comment

An old concept has been reused to advantage, as oral inflammation and infection were surgically and medically attacked among this small group of diabetic subjects. There is considerable theoretical conflict concerning the etiology of periodontal disease and gingivitis in all patients with or without diabetes mellitus. No characteristic organism or bacterial flora ever has been consistently implicated as causing periodontal inflammation. In the diabetic patient nutritional factors, such as subclinical vitamin deficiencies or previous periods of acidosis, may have featured as initial factors impairing local gingival metabolism. Resorption of alveolar bone and local abscess formation among the diabetics studied may have been on a neurogenic basis; however, there was no correlation between dental pathology and diabetic neuropathy. It is our clinical impression that diabetes mellitus and chronic, destructive periodontal disease are separate entities. Diabetes may be adversely influenced by the presence of periodontal disease, and conversely periodontal disease may be more severe in the diabetic state.

Trials of preoperative antibiotics for periods of 3 to 10 days in patients subjected to surgical treatment of periodontal disease produced no change in insulin requirements or in the state of diabetes. It was only after elective surgery had been accomplished that significant improvement in diabetic control was notable. It is therefore suggested that careful oral evaluation and periodontal survey be conducted in every diabetic patient.

Summary

Gingival and periodontal disease are common in young diabetic patients. Treatment of oral pathology by elective periodontal surgery and extractions where indicated may improve the practical regulation of diabetic patients. Periodontal therapy need not be confined to treatment of small areas. Treatment of the total pathology at one operation proved beneficial in selected patients.

COMPARISON OF ACUTE HYPOGLYCEMIC POTENCIES OF TOLBUTAMIDE AND CHLORPROPAMIDE

James W. Craig, M.D., Max Miller, M.D., Frank D. Mills
and
Naomi Nickerson, B.S., Cleveland

Tolbutamide and chlorpropamide were compared as to their intrinsic hypoglycemic action by statistical analysis of data obtained from 21 diabetic patients. The hypoglycemic agents, usually taken orally, were administered intravenously to avoid their possible differences in rate or completeness of gastrointestinal absorption. The blood specimens were drawn from the patients during three hours after administration of the drugs to assure comparison of their hypoglycemic effect at a time when the plasma concentrations would be similar. The specimens were analyzed for blood glucose and plasma levels of the two drugs. Each patient was tested once with each drug. The two drugs were found not to differ in their acute hypoglycemic potencies, and the need for a greater dosage of tolbutamide in long-term therapy is most likely explained by its more rapid rate of inactivation and excretion.

At present two sulfonylurea drugs are available in the United States for clinical use as orally administered hypoglycemic agents. These compounds, tolbutamide (Orinase) and chlorpropamide (Diabinese), are similar in chemical structure, are effective in the same general types of diabetic patients, and probably have a common mechanism of action. However, the orally given dose of chlorpropamide, which is effective in the prolonged therapy of diabetes mellitus, is usually less than that of tolbutamide.[1] The smaller dose requirement of chlorpropamide than of tolbutamide might be due to differences in the gastrointestinal absorption of the two drugs, differences in their rates of inactivation or excretion, or different intrinsic hypoglycemic potencies. In the present investigation the intrinsic hypoglycemic potencies of the two drugs have been compared. The drugs were administered intravenously to avoid the effect of possible differences in the rate or completeness of their gastrointestinal absorption. The studies were limited to three hours after administration of the drugs so that their blood glucose-lowering effects might be compared at a time when plasma concentrations of the drugs were similar; the influence of different rates of inactivation and excretion of the two drugs was thus eliminated.

Methods

The subjects for these studies were 21 hospitalized patients with diabetes mellitus. The diabetes was of the stable type in all subjects, with the possible exception of the patient in case 4, who had chronic pancreatitis. Each patient was tested at least twice, once with tolbutamide and on another occasion with an equal dose of chlorpropamide; doses of 1.0, 0.5, 0.25, or 0.125 Gm. of the sodium salts of the compounds were used. Patients 11 and 12 were tested at more than one dose level of the two drugs. The tests were performed with the patients resting in bed after fasting overnight. At the beginning of the test the subjects were free of the influence of exogenous hypoglycemic agents; they had received no long-acting insulin for at least 48 hours, no regular insulin for 15 hours, no tolbutamide for 15 hours, and no chlorpropamide for at least 96 hours before any of the tests. A 5% aqueous solution of the sodium salt of the drug was injected into a peripheral vein in one minute. Blood samples were obtained through an indwelling needle in a peripheral vein before and at 30-minute intervals after drug administration for a total of three hours. Blood glucose concentrations were determined by the colorimetric method of Somogyi[2] and plasma tolbutamide and chlorpropamide levels by the method of Toolan and Wagner.[3]

Ten replicate glucose determinations performed on each of three different samples of blood yielded a mean standard deviation of ±4.1 mg. per 100 ml.; the glucose concentrations of the three samples ranged from 108 to 122 mg. per 100 ml. Replicate determinations of tolbutamide in plasma gave an average standard deviation of ±1.1 mg. per 100 ml. at plasma levels of 2 to 20 mg. per 100 ml., and the corresponding figure for chlorpropamide was ±0.6 mg. per 100 ml. at levels of 1 to 20 mg. per 100 ml. The statistical significance of differences between blood glucose responses to the two drugs and between their plasma levels was assessed by analysis of the differences of paired observations.[4]

* In the calculation of the mean blood glucose decreases, a value was omitted if no corresponding value was available at the same time interval in the test with the other drug.

† Mean of individual differences (± one standard error) between blood glucose decreases after administration of tolbutamide and after that of chlorpropamide.

‡ Probability of greater than 95% that blood glucose decreases after administration of tolbutamide and chlorpropamide are different.

Results

As shown in table 1 and the figure, at all four dose levels, equal quantities of tolbutamide and chlorpropamide produced similar decreases in the blood glucose concentration during the three hours after drug administration. At no point did chlorpropamide exhibit a significantly greater hypoglycemic effect than tolbutamide. The mean plasma concentrations of the two drugs are shown in table 2. After two and three hours the average tolbutamide levels were usually slightly less than the chlorpropamide levels, but the differences were not statistically significant except at 180 minutes after administration of the 0.125 Gm. dose. At no time was the plasma concentration of tolbutamide significantly greater than that of chlorpropamide.

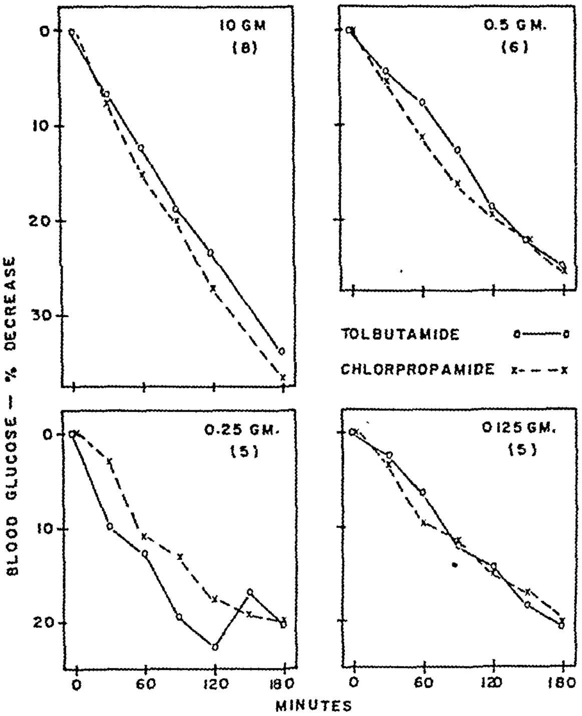
Comment

Observations by ot[illegible]orpropamide was more [illegible] in lowering the blood glucose concentration of normal or diabetic subjects within one to five hours after oral administration [5] are probably explained by the slower gastrointestinal absorption of the latter drug [6] rather than by a difference in the intrinsic hypoglycemic potencies of the two compounds. Tornow and co-workers [7] also compared the hypoglycemic effects of 1 Gm. of tolbutamide and an equal dose of chlorpropamide by giving the drugs orally to diabetic patients; during the four hours after administration, chlorpropamide therapy produced a slightly greater decrease in the blood glucose concentration than did tolbutamide, but the difference was not considered clinically significant. The results of subsequent studies by West,[8] in which the compounds were administered intravenously to normal subjects, confirm the finding of the present study that at equal plasma levels of the two drugs their acute blood glucose-lowering effects are of similar magnitude. Knauff and colleagues [1a] also found similar degrees of hypoglycemia during six hours after the intravenous administration of 30 mg. per kilogram of body weight of chlorpropamide or tolbutamide to normal or diabetic subjects. The same investigators [1a] reported that during long-term administration of tolbutamide or chlorpropamide to nondiabetic subjects the degree of fasting hypoglycemia was a function of the fasting serum sulfonylurea level and that on the basis of serum concentrations the two drugs were equally active as hypoglycemic agents. The findings of Forsham and co-workers,[1b] that lower serum levels of chlorpropamide are required for significant hypoglycemic effects as compared to tolbutamide, and the report of Stowers and colleagues,[8] that at the same blood level chlorpropamide produces a greater fall in the blood sugar level than tolbutamide, are difficult to reconcile with the results just described; neither of the reports states clearly whether these conclusions are drawn on the basis of comparisons of the two drugs in the same or in different subjects. However, most available evidence indicates that in the long-term therapy of diabetes mellitus the lower dosage requirement for chlorpropamide as compared to tol-



Comparison of acute hypoglycemic potencies of tolbutamide and chlorpropamide; mean decreases in blood glucose concentration produced by intravenous administration of equal doses of sodium salts of tolbutamide and chlorpropamide to same diabetic patients. Decreases are expressed in terms of percentage of fasting blood glucose concentrations. Number of patients tested with each dose of drugs is indicated in parentheses.

butamide is not explained by a difference in the intrinsic hypoglycemic potencies of the two compounds but by a slower rate of inactivation and excretion of the former drug[9]; as a result, higher serum drug levels are produced and maintained by a given dosage schedule of chlorpropamide.

Summary

Blood glucose concentrations and plasma drug levels were measured for three hours after the intravenous administration of tolbutamide (Orinase) or chlorpropamide (Diabinese) to diabetic patients. Each subject was tested twice, once with tolbutamide and on another occasion with an equal dose of chlorpropamide. At all four dose levels (1.0, 0.5, 0.25, and 0.125 Gm. of the sodium salts of the drugs) similar plasma drug levels and a similar lowering of the blood glucose concentration were produced by the two drugs. It is concluded from these results, and from the longer term studies of other investigators, that the two compounds probably do not differ in their intrinsic hypoglycemic potencies. The lower dosage requirement of chlorpropamide as compared to tolbutamide therapy is due to the higher blood drug levels maintained by a given dosage schedule of chlorpropamide.

NEED OF PSYCHOTHERAPY IN DIABETES.—Many young diabetic patients exhibit a gamut of unreasonable behavior which can be interpreted as essentially self-destructive. While similar behavior may occur in adult diabetics and in other chronic illness, it is in the young patient with diabetes in whom a conscious or unconscious self-destructive reaction to life problems is most prominent. Various aspects of the treatment of diabetes and the possible complications of the disease afford such patients ready means for self-destructive acting out. Such behavior is most frequently exhibited when major life adjustments must be made, and are more likely to occur when the emotional and socioeconomic environment is suboptimal. It is therefore essential in the treatment of juvenile diabetic patients to investigate the early manifestations of such behavior and to attempt to avoid more serious difficulties by manipulation of the environment and by a gentle, gradual adjustment of the young diabetic to a more realistic view of his illness and his problems. Since the situation is usually irretrievable when self-destructive ways of handling diabetes have become an accustomed behavior pattern, it would be desirable to interview young diabetics psychiatrically at the onset of the disease and periodically thereafter.—S. Stearns, M.D., Self-destructive Behavior in Young Patients with Diabetes Mellitus, *Diabetes*, Sept.-Oct. 1959.

RETURN TO WORK OF PATIENTS WITH ANGINA PECTORIS AND/OR MYOCARDIAL INFARCTION

Robert S. Green, M.D.
and
Erna L. Borousch, M.D., Cincinnati

In the experience of the authors it has never been necessary to resort to surgical procedures to relieve a patient of anginal attacks. Considerations here outlined have led to a program for building up collateral circulation in the coronary vessels in anticipation of eventual coronary occlusions or excessive demands on the myocardium. It is insisted that the patient be underweight. Factors inducing anginal attacks must be eliminated, and nitroglycerine must not be misused simply to escape the penalties of overburdening the heart. During subsequent rehabilitation the patient should be concerned more about returning to his job than to his advocations. In 13 years of experience with the type of patients here specified, relief from the symptoms of angina, even of the so-called intractable type, has been achieved in all patients who adhered to the plan, and most of them have returned to their former occupation.

The problem of return to work of patients with angina pectoris, myocardial infarction, or both, has been of particular interest to us in the Memorial Heart Laboratory of St. Mary's Hospital, which has every facility for advanced cardiovascular study, including surgery. The reason for our interest lies in the fact that medicine is passing through a period when heart surgeons try practically any procedure to get into this field, e. g., sprinkling of talcum powder, superimposition of omentum, anastomosis of vessels, ligation of vessels, replacement of vessels, and others. One of us (R. S. G.) has been involved in this problem since 1946, when, as a fellow, he was asked by Drs. Nicholas Carter and Johnson McGuire to obtain patients with severe angina who would be suitable candidates for a new technique of grafting lung tissue on the heart to improve collateral circulation.

The answer given in 1946 has not changed some 13 years later. We have never seen a patient with arteriosclerotic disease of the coronary arteries in whom surgery was necessary to control angina. By adhering to simple rules of living and treatment we believe these patients do a better job of growing their own collateral blood circulation than surgeons can ever hope to stimulate or implant in them. The basic considerations that led to this conclusion are as follows: 1. 77.3% of young soldiers (average age 22.1 years) on whom autopsy had been performed in Korea had gross evidence of coronary artery disease.[1] 2. If a grade 1 change is considered as minimal arteriosclerosis of the coronary arteries and a grade 4 change one where a major vessel is completely occluded, then a grade 3 change is severe. In one autopsy series of 600 cases,[2] 18% of men between 30 and 40, 40% between 40 and 50, and 75% between 50 and 70 years of age had grade 3 arteriosclerosis of their coronary arteries. In another autopsy series of 950 cases,[3] 40% of the subjects between 18 and 39, 75% between 40 and 49, and 82% of over 50 years of age had severe advanced coronary arteriosclerosis.

The conclusion to be drawn is obvious. The majority of men past the age of 20 years have arteriosclerosis of their coronary arteries, and these changes are advanced by the time these persons are 50 years of age. The answer to this problem, in the child as yet unborn, may lie in preventing such changes through diet and advanced knowledge of stress reaction, but this answer is not good enough for us or for our patients. Let us not fool ourselves—we must contend with coronary arteriosclerosis now.

The crucial and consoling fact is that practically everyone who dies at the age of 90 years has severe, advanced disease of the coronary arteries, often with occlusion of as many as five or six major vessels. Frequently such a person has never had a symptom and died from pneumonia rather than heart disease. Our hope must lie in what caused these persons to reach the age of 90 years, despite advanced disease; our concern must be why others die young, despite relatively minor changes in the coronary arteries.

A clue to the solution is found in the animal experiments of Blumgart and co-workers[4] who used a modification of the coronary artery injection technique of Schlesinger.[5] Young pigs were selected for the study because their heart circulation is com-

---

From the Memorial Heart Laboratory, St. Mary's Hospital.

Read in the Symposium on Current Concepts of Heart Disease and Employment before the Joint Meeting of the Section on Diseases of the Chest and the Section on Preventive Medicine at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 10, 1959.

parable to that of human beings. In general, when a major coronary vessel was suddenly occluded to less than 13% of the original cross-sectional area, the pigs died within 20 minutes. However, when the vessel was partially occluded at a first operation and then totally occluded some two weeks later, a significant percentage survived due to development of collateral blood vessels. In several animals the collaterals were functionally adequate and there was no gross evidence of myocardial infarction.

This is the key to the problem. It is not the occlusion of a blood vessel as such that concerns us but the extent of the collateral circulation at the time of closure. More important, an adequate collateral circulation may develop with time so that an infarction will not occur when the artery is occluded. Time, therefore, is the key to the solution. Treatment consists of reducing the work demands of the heart as much and as long as necessary to prevent any myocardial oxygen deficiency. As collateral vessels develop and the potential oxygen supply to the myocardium increases, the patients are permitted to return gradually toward a normal existence. It is important to remember that a coronary circulation that is adequate for myocardial needs at rest may be inadequate for an increased work load of the heart. This resultant unanswered oxygen deficit is considered to be the cause of angina pectoris and probably accounts for the cases of acute myocardial infarction that have been reported in the absence of fresh narrowing or occlusion.[6] A final important consideration is that the growth of collateral blood vessels is a relatively slow process.[7] Success in treatment will be in direct relation to the ability of the physician to restrict any increase of the work of the heart within the capacity of this gradually increasing circulation to deliver an adequate supply of oxygen to the potentially deficient myocardium.

Subjects and Procedures

In the clinical approach to this problem, we regard all men and those women with hypertension or diabetes as having disease of the coronary arteries. The only question we ask ourselves is whether the coronary arteries and collateral circulation are adequate to supply the oxygen necessary for the work demands placed on such a person's heart. The work load of the heart is determined by intrinsic or extrinsic factors. The intrinsic factors are too often forgotten. We can reduce the work of the heart by weight loss, lowering of high blood pressure, correction of anemia, proper control of thyroid function, supply of needed vitamins, and recognition and compensation of heart failure, particularly in the early stages when it is usually overlooked. Unusual fatigue, insomnia, or a change in the shortness-of-breath pattern may be the first evidence of cardiac failure, and digitalization often alleviates these symptoms and reduces the incidence of angina pectoris. These intrinsic factors must be considered because they are important. However, for purposes of this presentation we will consider them not present or treated.

The extrinsic factors affecting the work load of the heart stem from a world where one has to run to stand still. It is of interest that the list of factors that raise blood pressure in a normal person is comparable to the list of factors that precipitate angina, i. e., fatigue, emotion, walking, strenuous activity, meals, and cold. There is evidence that an elevation of blood pressure increases the work of the heart and results in reflex constriction of the coronary arteries. It is our concept that the transient elevations of blood pressure produced by these factors result in an oxygen deficit of the myocardium in patients with an inadequate collateral blood circulation. This deficit is usually accompanied by angina, a change in the electrocardiographic pattern, or both. This concept explains, to us at least, why angina is usually associated with a rise of blood pressure and relieved as the blood pressure falls. The easy way to facilitate a fall of blood pressure is, of course, the absorption of 1/200 grain (0.30 mg.) of nitroglycerine under the tongue.

The main approaches to the evaluation of a patient's myocardial circulation versus his cardiac work load are (1) taking a painstaking medical history, since the principal evidence of the disease is a symptom; (2) a careful physical examination; (3) laboratory studies, including an electrocardiogram and radiologic evaluation; and (4) the physiological response of the myocardium to induced strain. The importance of careful study is twofold: 1. The majority of persons are heart-conscious and have pains of one sort or another in their chest, arms, neck, and abdomen. 2. It is as serious a mistake to incorrectly diagnose angina pectoris as it is to overlook a case of angina masquerading as indigestion.

What is angina? Angina is always definite, never vague. It is usually substernal but may be manifest only by a pain in the wrist or in the region of the jaw. The patient knows when the sensation is there. He knows when it is gone. It recurs in a set pattern for any given area of oxygen deficiency in the heart. It starts in the same place, in the same way, and proceeds in the same manner. It is brought on by a definite set of factors that increase the heart's work and are learned quickly by the patient. It is relieved by eliminating these factors: if brought on by walking, it is relieved by standing still; if brought on by excitement, it is relieved by calming down. The patient learns that he can walk slowly on level ground and avoid an attack of angina. He knows that if he walks fast, uphill, or into a cold wind an attack may be provoked.

It is of interest that sensitivity to such work factors varies in individual persons. We have had patients develop angina after walking a short distance, while others can walk long distances but have an attack of angina at the slightest exposure to cold. These factors may be parlayed: a man may mow his yard without difficulty in the morning but have angina when he mows it in the evening, after a tiring day; he may walk one block without difficulty before having a meal but have angina with the same exercise, after having had a meal.

An attack of angina always lasts longer than 30 seconds and rarely longer than 15 minutes, unless myocardial infarction has occurred. It is not affected by breathing, touch, or body motions, such as twisting or bending. It does not occur at night, unless it has occurred during the day. The only exceptions we have found to the latter statement were one patient who had severe nightmares and another who was a night watchman.

This brings us to a consideration of fatigue, the most important factor of all, particularly when we consider therapy. Angina is usually an afternoon or evening disease when a patient has relatively less heart reserve, and this fatigue factor interacts with other precipitating factors. We recently saw a patient who walked to work uphill after breakfast without trouble but had an attack of angina on the way home, walking down the same hill, and who always ate at home, even though he lived alone, because the angina was worse if he ate before he walked home.

How important is fatigue? In our experience most patients who had their initial episode of myocardial infarction were in a state of chronic mental or physical fatigue at the time of the infarction. We believe fatigue not only is the earliest symptom of impending coronary insufficiency but also is the most important extrinsic factor in aggravating this condition.

If the diagnosis is clear from the history or from other findings, we usually do not perform tests that increase the oxygen need of the heart. However, when the high incidence of severe disease of the coronary arteries in males is considered, it is obvious that most patients with this potentially vicious process are without symptoms and have normal objective heart findings on physical examination, electrocardiogram, and x-ray of the chest. It is the apparently normal patient and the one who represents a doubtful case who are subjected to graded activities, accompanied by electrocardiography—the so-called tolerance tests. A two-step exercise test is performed first. If results are normal the exercise test is repeated the next day, the patient holding ice cubes in the hand; then it is repeated with ice cubes after a tiring day, and next with ice cubes after a tiring day and a large meal, and finally after a large, black cigar has been smoked. A lively argument by the patient with his wife prior to the final test is desirable. The full gamut of these tests is not routine by any means. However, if the patient survives these experiences we believe we can pat him on the back and reassure him about his coronary and collateral circulation without too much fear that he will drop dead as he leaves the office.

As stated before, we consider all men past the age of 20 years and women with diabetes or hypertension to have coronary artery disease. On the basis of these tests, their heart circulation is classified into four categories, which are as follows: 1. Those who have an adequate heart circulation. They have no symptoms or other evidence of disease and have no change in their response to heart strain. 2. Those who have an inadequate heart circulation which is manifested only by the heart strain tests. Patients in this group have no symptoms or other evidence of disease. 3. Those who have a serious deficiency of heart circulation to such a degree that they have angina, severe changes in their electrocardiograms, or both, with minimal exercise. 4. Those who have evidence of a recent myocardial infarction and thus have moved from group 3 to 4.

Treatment

Our approach to treatment is not directed toward the prevention of further coronary arteriosclerosis. We assume that this process is present and that it will progress. Our aim is to develop an adequate collateral circulation in advance of occlusion or unanswered myocardial oxygen demand.

Group 1.—The rules which apply to all men past the age of 20 years and to women with diabetes or hypertension are as follows: 1. All intrinsic factors that increase the heart's work load are corrected. This is especially true of weight, and we insist that patients be underweight. 2. We assuage patients' fears by pointing out that, in fact, we doctors and all their friends are also members of the arteriosclerotic-coronary "team," and, in the honest belief that this is true for most of these patients, we tell them that they are capable of attaining an age of 90 years, despite angina or infarction. 3. We discuss with patients the problems of coronary arteriosclerosis in common-sense fashion, to give them a realistic understanding, and we explain to them the concept of collateral blood circulation and how it will build up, given time. They are told that, although we do not know the specific factor necessary to stimulate collateral blood vessel growth, our experience indicates that collateral circulation will grow in advance of heart demand for practically any activity, provided the following three simple common sense rules are observed.

First, patients must act their age, in the sense that a ball player aged 35 cannot run as well as one aged 25, even though we doctors cannot detect a significant difference.

Second, patients must get into condition before attempting any new activity. Neglect of this rule explains why so many of them die of heart attacks while shoveling snow or hunting—they did not condition themselves for either of these pursuits. The young baseball pitcher gradually increases his activities each spring, first engaging in a few pitches, then one inning, and next several innings, before he attempts a full game. Our patients would not have thrown an arm away when they were young, and yet, unconditioned at the age of 50 years, they throw their heart away when it is not ready for the strain imposed by certain activities. There is a second important point about conditioning. To be in condition for one thing is not necessarily to be in condition for another. An athlete in perfect condition to run 100 yd. is not in condition to swim 100 yd. rapidly. This reminds us of the story of a patient who had a myocardial infarct. His work demanded climbing a flight of steps eight times a day. We had trained him for this activity over a period of months, making him walk first a few steps, then one flight of stairs, next two, and so forth. He returned to work and did well for 18 months, when he had another attack of angina. He said he got it polishing the rail while climbing the steps. We censored him. "We trained you to climb steps, not to polish rails. If you want to polish rails, let us know and we'll train you for that."

Third, and most important, is the common-sense advice to avoid physical or mental fatigue. Our contemporary pattern of fatigue, topped by an unusual degree of mental or physical strain, is taking its toll, no doubt. Nevertheless, one may wonder whether we are not deceiving ourselves. We often have seen executives who were harassed and overworked before they had a myocardial infarction but who became better executives after the infarction when they "put their feet up on the desk" and became "thinkers." Their fire ball gone, they "fool" their business problems with curves. The sad thing is that they need not have lost that fast ball in the first place.

Group 2.—In addition to the above, patients with a minor deficiency of heart circulation which is revealed only by exercise tests are cautioned to stay away from unconditioned, strenuous activity for several months but to lead an otherwise normal life.

Group 3.—This group of patients with severe coronary and collateral deficiency and angina pectoris demands our most careful attention. We must correct even the slightest deficiencies of the intrinsic factors that increase the work load of the heart, such as anemia, overweight, and others, and we must recognize and treat congestive heart failure early, because, *in our experience, the heart in failure* cannot rebound without help. A myocardium that does not put out an adequate supply of blood to the coronaries may be just as important a factor in angina as aortic stenosis which blocks the flow.

The moment a patient has angina he has an oxygen deficiency that injures his heart muscle, and if he injures the muscle often enough it will be replaced by scar tissue. To this group we apply the fourth rule of common sense—avoid attacks of angina at all costs. It is just common sense to know that if one can get angina by walking fast and avoid it by walking slowly, it would be wise to accept God's warning and walk slowly; or if angina comes with large meals, to eat small meals; or if it comes with walking up steps, to use the elevator.

At this point, special attention is given to the instruction of the patient who has had angina pectoris. He is worried and has focused on the multiple, small chest pains that everyone has had since childhood. We teach him how to recognize the pain that counts, the one that constitutes angina. Of greatest help in recognition is the duration of pain. "Does it last 30 seconds?" We keep time as the patient imagines the duration of his pains. Thirty seconds is a long time. Most of the nonsignificant "stitches in the chest" last but a few seconds.

We never give patients nitroglycerine at this stage of treatment. These patients, provided they do not fall into one of the four categories to be mentioned below, are allowed a trial period of one week to change their pattern of living in an attempt to prevent angina. If these patients can avoid attacks of angina, they will be able to increase their activities in time, as they become conditioned and as collateral blood vessels develop.

If, by following these rules, the patient is able to avoid angina, he is allowed to progress slowly back toward normal activity, always ready to draw back, however, if attacks of angina recur. At this time he is given nitroglycerine as a "spare tire" but is never allowed to abuse this privilege; he takes it if pain occurs or he takes it prophylactically if he cannot avoid breaking the therapeutic rules.

There are four types of angina pectoris, all serious evidences of an inadequate collateral circulation, that require more stringent treatment than the above: (1) angina that is not controlled by the above regimen, (2) an increase in the frequency of angina pains, (3) any one angina attack that lasts longer than 20 minutes, and (4) angina at rest. The latter is a late stage of this disease. The heart circulation in these patients is not adequate even when they are resting.

These four types of angina are the predecessors of myocardial infarction. These patients are treated just as if they had an infarct, in an attempt to establish collateral circulation and prevent infarction, with three weeks of bed rest after their last *pain, anticoagulants, and other measures—i. e., just* as the fourth group of patients with a recent infarct.

During the first week of this three-week period we adhere to every measure which lessens the load of the heart, such as quiet, sedation, no visitors, a

500-calorie diet, no strains or movements, including bowel movements, feeding by nurses, and so forth. We do not hesitate to use an oxygen tent for patient restraint as well as for inhalation therapy. Patients are told that this is akin to the spare tire on their car and that it is a part of our mutual game of the moment, i. e., "playing all our cards close to the chest."

The avoidance of bowel movements is an example of the meticulous attention paid to any unnecessary increase of the heart's work during this treacherous stage. The evolution of the method is worth comment. Some 12 years ago, concerned by the frequency of tragedies induced in these patients through bowel movements, we investigated the physiology of bedpan deaths.[8] This was followed by several years of fruitless endeavor to develop a practical method to negate the severe strains of the bear-down Valsalva maneuver. We did evolve an effective method of sorts, i. e., keeping the glottis open and breathing out during the period of straining. Practice of this method, however, resulted in far more physiological upset than occurred with the most difficult bowel movement. We remained at a loss as to how to gauge strain until about 10 years ago, when, after use of a commode by one patient had led to tragedy, we asked ourselves the question we should have asked in the beginning of the study: "Are bowel movements really necessary at this time?" In most cases they are not.

We have more than 200 patients who have gone through the first 12 days after acute myocardial infarction without a bowel movement. A 500-calorie, low-residue diet leaves but little to move; administration of a small amount (10-15 cc.) of mineral oil each night prevents fecal impaction. One patient in whom resumption had been overlooked requested permission on the 21st day for a bowel movement. In response to our surprised questioning he stated, "Doctor, my bowels only move at your command." Failure to prevent a first bowel movement sometimes occurs in the recently engorged patient. Complete failure of obstipation is found frequently in those elderly women who are addicted to taking cathartics and enemas; they consider a missed bowel movement a greater sin than missing church and will have no truck with these silly, new-fangled ideas.

About the second week, or three days after the temperature is normal in patients with infarcts, we start a graded increase in activity whereby, at the end of the third week, patients are allowed to sit up in a chair for one hour, three times a day. By the middle of the fourth week they are up and about the room. They are discharged as soon as they are able to go through the same daily routine in the hospital that they will have to engage in at home. Then, they are subjected to about one week of a graded increase of activity on the same floor level, followed by a trial climb of one flight of steps per day, short walks in good weather, and short rides in an automobile when someone else is driving.

These patients usually are ready for an office visit six weeks after the beginning of hospitalization. The basic rules are always stressed: act your age, get into condition before you attempt any new activity, and avoid fatigue. About seven weeks after hospitalization they are ready for job training. The work circumstances are analyzed, and the patient is conditioned for each one, such as walking up a hill to get to the bus, climbing steps, or lifting objects. When we feel that patients can perform their duties on this simulated basis they are allowed to return to work, first for a few hours in the morning, then for a full morning, next for a full day after a week-end, and so forth until they are working full time. As might be expected, the greatest difficulty, particularly with regard to fatigue, comes at the end of the work week.

In our experience, a patient with angina severe enough to necessitate hospitalization needs more careful supervision than one who has had an infarct and in whom scar tissue has replaced heart muscle. This is logical, since the oxygen demands of viable myocardium are greater than those of scar tissue.

There is an important philosophy that must be imparted to patients at this stage, namely, that a man is not happy unless he can do his job and that our only concern at this time is his job. Bowling, golf, and similar pursuits are frills with which we deal only later, when we are certain that a patient's heart circulation is adequate for performance of his job.

Throughout this course of rehabilitation the patient knows he may have to draw back to an earlier stage of activity if symptoms develop. This is particularly true of fatigue. We rarely see a patient who, observing our common-sense rules and with a recurrence of angina, has not had fatigue first. In other words, we believe fatigue is a symptom that occurs before the symptom of angina appears.

As time goes on we introduce the frills into these patients' lives in exactly the same manner as we prepared them for work. In golf, for example, they first hit practice shots, then play a hole or so on level ground on a fine day, and so forth.

Today, we are always confronted with the question about drugs and diets that may lower the blood cholesterol level. We do not use them. Patients who see the "cholesterol sword of Damocles" poised over every bite of food are miserable; our only instruction to patients, after weight reduction, is to eat high-protein and low-fat foods—"eat the meat, cut off the fat." Perhaps cholesterol and its allies are the predecessors of further "pipe rusting"; perhaps this may be prevented by soul-searing diets or expensive drugs; or perhaps not. This reminds us of the man whose doctor advised him that he would live to be 80 years of age if he abstained from smoking, drinking, and women. He died of shock on his 75th birthday immediately after finding out his doctor had been wrong. We assume the pipes are rusting, the same way the hair is graying and the wrinkles are wrinkling.[6] Our only concern is to grow an adequate supply of collateral blood vessels in advance of "rusting" by following the common-sense rules outlined above. This is what was done by a man who, despite occlusion of six major blood vessels at some time during his life, none of which ever bothered him, died of pneumonia at the age of 90 years.

Therapy with anticoagulants in ambulant patients is another method of promoting chronic invalidism. We reserve use of anticoagulants for the relatively few patients whose myocardium has been replaced by scar tissue to such a degree that cardiac failure is a constant threat. We believe the greatest value of anticoagulants lies in prevention of complicating thrombosis and infarction in other organs, such as the lungs. In general, we do not use the long-acting nitroglycerine-like compounds. We believe that angina pectoris, like the blinker lights at the railroad crossing, is a valuable warning of impending trouble.

Smoking is forbidden during the treacherous days before angina or infarction has been brought under medical control. Subsequently it is cautioned against but allowed. We have observed only two patients in whom smoking was a precipitating factor in producing an attack of angina. Patients are allowed to drink, they are urged to take routine vacations that are really vacations instead of energy users, and they may have relations with their wives. No wonder they like us and follow our suggestions.

Results

Is this method of treatment infallible for everybody? Of course it is not. There is a hard core of disbelievers who, once they feel well and do not have pain, will extend themselves, will gain weight, and will get into trouble. They want pills, not common sense. The percentage of disbelievers will be in direct proportion to the skill of the physician as salesman and practitioner of the art of medicine —his ability to show kindness toward and a sincere interest in his patients. There is a second group of patients who, for financial reasons, short-circuit the approach suggested by us. In both groups a second infarct or the recurrence of symptoms often converts a patient to a believer. There are patients who form a third group. Their heart muscle has been replaced by scar tissue due to an extensive infarction or repeated infarction. Their heart circulation is good, but they do not have the muscle to do the job. It is interesting, however, to note how very few patients cannot be returned to at least a comfortable existence.

The proof of any method of treatment is in the results. We have been using this common-sense approach for some 13 years. Our patients have returned to all types of work. One patient, first seen after his third infarct, has been working full time as an automobile mechanic for eight years without an episode of angina. His hobby is fishing of a relatively strenuous nature, namely, casting from a boat in the northern woods. He has completed his sixth annual vacation and is planning for his seventh. Others are driving trucks, lifting heavy objects, digging ditches, and climbing steps as insurance collectors in poorer districts where three flights for 50 cents is the usual work load.

We get repeated requests in the Memorial Heart Laboratory to study newer drugs for treatment of angina pectoris. We need this income, but our answer is always the same. "We do not have patients with angina who do not respond to this common-sense method of treatment, so why use drugs?"

As stated in the introduction, we are the diagnostic part of a heart surgery team. We respect the ability of these surgeons and the advances they have made possible in the field of heart disease, but we never have had a patient in whom an operation was considered necessary to control angina, to return him to a gainful occupation, or to enable him to live longer.

The patient response to our regimen is excellent. They like this approach: Their health is in their own hands. There is no magic. The dread outlook that used to accompany angina and infarction has been lifted. They are given simple rules that make sense—to act their age; to condition themselves for new activities; to avoid fatigue; and to avoid an attack of angina pectoris itself. As they first crawl, then walk, and next return to work and, finally, to the frills of life, such as dancing, golfing, and fishing, their confidence in themselves and in their physician grows. The role of the physician is now that of teacher and disciplinarian. This means careful instruction of patients and regular consultations, to either praise them for good performance or let them know the physician's displeasure when they stray from the rules. Our satisfaction is in relieving their worries and in guiding them to the acme of their capabilities, while retaining a margin of reserve for emergencies. "Not too warm, not too cold, but just right."

Summary

Studies by other investigators of the pathology and physiology of the circulation of the heart indicate that a narrowing of the cardiac arteries and an associated growth of collateral blood vessels is *an inherent process in practically all men past the* age of 20 years and in women with diabetes or hypertension. In some patients, functionally adequate collateral vessels develop to such a degree

that the narrowing or closure is of no clinical significance; in others, the rate of narrowing exceeds the rate of development of collateral vessels so that coronary insufficiency even to the point of infarction occurs.

Our experience indicates that functionally adequate collateral blood vessels grow in advance of significant narrowing, provided abnormal intrinsic factors that increase the work load of the heart and myocardial oxygen demand, such as obesity, anemia, hypertension, congestive failure, and others, are corrected, and provided patients follow three rules of common sense, i. e., to act their age, to get into condition before attempting any new activity, and to avoid unusual physical or mental fatigue. A fourth rule of common sense is applied to patients with angina pectoris, namely, that they avoid angina at all costs.

Patients who are not able to avoid angina or who have an increase in the frequency of angina, any one attack that lasts longer than 20 minutes, or night angina are hospitalized and treated as if they had a myocardial infarction. The growth of a functionally adequate collateral blood circulation in patients with angina pectoris or myocardial infarction is a product of months rather than days. Extreme care by the physician is mandatory to insure that the myocardial oxygen demand never exceeds the ability of the cardiac arteries to supply oxygen during this period. Relief of the symptom of angina, even of the so-called intractable type, has been accomplished in all patients who, treated over a period of 13 years, have adhered to this common-sense medical management.

Most of these patients have been returned to a full work status, regardless of occupation. Failure to return to previous work has been based on associated lesions, such as valvular heart disease or emphysema, and not because of an inadequate heart circulation.

Surgery has never been considered necessary to control symptoms, to prolong life, or to increase work capacity. It is apparent that patients do a better job growing their own collateral circulation than surgeons can ever hope to stimulate or implant. In general, drugs and diets that control blood cholesterol and lipid levels and drugs that lower the prothrombin time have not been found necessary.

Research attention should be focused on the basic methods whereby a collateral circulation develops and on methods of preventing narrowing or closure. Studies along these lines are in progress.

DETERMINISM OR FREE WILL?—Deceptive is the theory that all cause for human actions lies in definable conditions, thus all can be explained and justified, not condoning the evil things people sometimes do, but ascribing their destructive behavior to factors beyond their control. Better it is, it seems to me, for man to accept the more divine belief that he is responsible for himself, that purpose can be a substitute for aimlessness, that conditions can be overcome by the power of the human will, that self-indulgence and ego-centric motivations have never, in all history, served to satisfy the inner cravings of the human spirit. Rather, there is always the window to wash, if it be clouded; the sun to be met at dawn, rather than to be curtained by opaque animal comfort; rivers of experience to be forded despite the hazards of the flood.—C. F. Hansen, Ed.D., Mental Health Aspects of Desegregation, *Journal of the National Medical Association,* November, 1959.

EVALUATION OF THE CARDIAC PATIENT FOR WORK CAPACITY

Joseph G. Benton, M.D., Ph.D., Brooklyn, N. Y.

The relative importance of physical activity and emotional stress among the occupational factors leading to heart disease has been difficult to determine from a review of published data. There is also a lack of reliable tests for evaluating the work capacity of cardiac patients. In order to assess the strain of a given job it is necessary to consider not only the average energy requirements but also the peak loads. Experience has shown, however, that workers who return to properly selected productive employment after recognition of their cardiac disability have at least as good a prognosis as those who do not return and that with respect to efficiency, regularity of attendance, freedom from accidents, and adaptability they compare favorably with other groups of workers.

It has been suggested that there has been an increase in the incidence of coronary artery disease in recent years. This disease of modern civilization has assumed prominence during a period in which heavy labor is less common and the length of work hours has decreased while other pressures have increased. Constitutional factors are important in coronary artery disease, but there is also some evidence of variation of its incidence with environment. In addition, its relationship to physical effort is highly controversial, with, in many instances, significant medicolegal connotations.

Special interest in the general area of physical activity related to coronary artery disease originally stemmed from experience with numerous patients undergoing rehabilitation whose hemiplegia was a complication of underlying systemic cardiovascular disease. These patients passed through a graduated program of retraining, including, among other procedures, activities of daily living and ambulation ranging from level walking to stair-climbing of varying intensity. While complete follow-up data for these patients are presently not available, only rarely did their cardiovascular status deteriorate clinically while they were under observation. In this connection, it should be emphasized that rehabilitation was not considered feasible in any patient in whose case (1) there had been such cerebral damage as to preclude adequate mentation to allow for recall of retraining techniques, (2) the malignant phase of arteriolar nephrosclerosis had supervened, or (3) intractable congestive heart failure or coronary insufficiency was present. Indeed, these were considered contraindications for patient selection.

Review of Literature

Review of the literature indicates that there are divergent opinions about the relationship of effort or stress to coronary thrombosis. One group believes that coronary thrombosis almost invariably occurs in the absence of effort, usually at night and often in the early morning hours, when the blood pressure is low and the coronary blood flow diminished. Some maintain that angina pectoris is almost always precipitated by stress, either physical or psychological, and that this is related to coronary insufficiency in roughly 50% of cases but is coincidental in the pathogenesis of coronary thrombosis.[1] Others believe that there is good evidence that sudden, exceptionally heavy physical exertion may be followed by coronary occlusion.[2] In addition, there are those who believe that acute psychological disturbances may have a direct bearing on coronary occlusion.[3] All are agreed, however, that preexisting intrinsic coronary artery disease must be present.

With reference to psychosomatic factors in the pathogenesis of this syndrome, it is of interest to note that there have been described[4] increased capillary permeability and hemorrhage, hemoconcentration, and hypertension or hypotension (depending on the intensity of the stress) during the alarm reaction of the "general adaptation syndrome." In addition it has been demonstrated that significant changes in hemodynamics and electrocardiographic patterns occur during psychiatric interviews relating to stressful life situations.[5] Exercise and emotional stress have also been shown to cause not only changes in blood pressure but also an increase in blood viscosity and hematocrit value and a decrease in sedimentation rate and coagulation and prothrombin times.[6] It would appear, therefore, that there is objective evidence of the influence of physical and emotional factors on the vascular tone and the clotting mechanisms of the blood and that the central nervous and endocrine systems may be involved.

From the Department of Rehabilitation Medicine, College of Medicine, State University of New York, Downstate Medical Center, New York City.

Read in the Symposium on Current Concepts of Heart Disease and Employment before the Joint Meeting of the Section on Diseases of the Chest and the Section on Preventive Medicine at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 10, 1959.

The suggested increase in coronary artery disease is not due simply to an increase in coronary atheromas. Other conditions are necessary, and the complex of atheroma, thrombosis, and the capacity of the heart to deal with these in relation to the demands made on it is an important consideration. Some information relative to this has appeared in the American literature, but the most extensive surveys in this connection have been made recently by the Social Medicine Research Unit of the Medical Research Council of Great Britain.[7] It was hoped that these studies would afford knowledge of coronary artery disease as a public health problem and also that possible social factors which may be favorable or unfavorable to its incidence might be delineated.

The occurrence of coronary artery disease in certain groups of weekly paid employees of the London Transport Executive during 1949 and 1950 was carefully studied in approximately 31,000 men aged 35 to 64. The experience of drivers and conductors of the "red" buses (double-decker), drivers and conductors of trains and trolley buses, and motormen and guards on the underground railways was observed. Analysis of the data suggested that coronary artery disease occurs differently in the drivers (sedentary) and in the conductors (active). Angina pectoris was relatively more common among the conductors, whereas rapidly fatal coronary thrombosis was more common among the drivers. Of the first episodes among the drivers 13% took the form of angina—or were so diagnosed—compared with 39% in the conductors. Contrariwise, the "immediate" deaths accounted for 31% in the drivers (25 "immediate" deaths in 80 cases) as against 19% in the conductors. The conductors therefore had less lethal coronary artery disease than the drivers, and the disease seemed to be appearing in them at a later age. What disease the conductors had was less severe, with a smaller early case fatality as well as a lower incidence and therefore a substantially lower early mortality. On the other hand, the conductors manifested more of the benign type of disease, in the form of angina pectoris, than the drivers. These observations were judged reliable, since there was a triple check on the diagnoses—by the men's own general practitioners, medical officers of the London Transport Executive, and, in addition, corroboration in over 90% of the cases through documented confirmation by a specialist or a hospital, or both. Most significant is that this was an epidemiologic study of the experience of different occupational groups. The population consisted of men from the same part of the country, served by the same health and welfare services and living in broadly similar social circumstances during the same period of time. Conditions of sickness absence and benefit were similar throughout for the population studied.

The differences in figures between drivers and conductors are considered significant ($p<0.001$) when statistically analyzed, and therefore they would appear not to be due to faulty data or small numbers. Possibilities for the observed variations are as follows: 1. There may be differences in constitution and early experience of the conductors and drivers, one expression of which is that the men select their different jobs for themselves. 2. While there may be mental strains in both driving and conducting, these may be of different kinds, and this difference may be a factor in the higher incidence and mortality among the drivers. 3. The greater physical activity of "conducting" on the double-decker vehicles may be a cause of the lower incidence and mortality in the conductors.

The latter seemed the most likely explanation, and the hypothesis was tested by making a similar two-year study of the mortality and morbidity statistics referable to coronary artery disease in 110,000 men, 35 to 59 years of age, who were postal workers and civil servants and whose work involved three major categories of physical activity.

The results showed that the total incidence of coronary artery disease is lower in postmen (active) than in the sedentary workers. Their case fatality was also lower: one-third in the postmen (57 of 171), compared with almost one-half in telephonists, executives, and clerks (70 of 143). Again, as with the transport workers the early mortality of the physically active group (0.6 per 1,000) was substantially less than that of the physically inactive (1.2 per 1,000). On the other hand, the incidence of angina was higher in the postmen than in the sedentary workers (0.7 as against 0.5 per 1,000). The grades of postal employees which are "intermediate" with respect to physical activity showed total incidence and early mortality that lay, on the whole, between those of the postmen and the sedentary workers.

The experience of the postal workers and the civil servants may therefore be said to resemble that of the transport workers: The physically active group (the postmen) have less coronary artery disease, and what disease they have is less severe. It would thus appear that the data strongly suggest that physical activity at work is important in relation to the incidence of coronary artery disease in middle-aged men.

Further confirmation of this premise was afforded by an analysis of the mortality due to coronary artery disease related to strenuousness of work in the total male working population aged 45 to 54 in England and Wales from 1930 to 1932. Briefly, the mortality from coronary artery disease of the groups doing physically heavy work was less than one-half that of the light workers. If there is a major psychological factor operating to produce the mortality gradient already noted, the scatter of the sample suggests that it is so intimately associated with the physical factor as not to be readily distinguishable from it. The early observations of 1930-1932 were corroborated by analyses of records of men aged 45 to 74 dying of coronary artery disease in London and the home counties in March, 1952. This would tend to obviate the technical question of possible variations in diagnoses.

Of special interest, and in some respects contradictory to the previous general conclusions about the relationship of type of work and coronary artery disease, are data on physicians. A study[8] was made of over 6,000 male medical practitioners in Britain, aged 35 to 64, who held "immediate" noncancelable sickness insurance. The incidence of first attacks of coronary artery disease from 1947 to 1950 was twice as high among the full-time general practitioners aged 40 to 64 as it was in full-time consultants or specialists and public health officials. When "G-P specialists" were added to the full-time general practitioners, the incidence in the composite group was 1.8 times that in the remainder. Finally, the incidence of coronary artery disease in a large group of nonmedical men of comparable age in the civil services, the professions, and industry was well below that of the full-time general practitioners and resembled that of the other physicians. A comparison with the provisional mortality from coronary disease among the men of comparable ages of England and Wales in 1950 gave similar results. Comparable data have been presented in studies done in this country in 1947-1948.[9] It is possible that the well-known day-to-day stress, other than physical, under which the average general practitioner operates, may be a causative factor for the increased mortality in this group. Such factors, not the least of which may be psychological, would admittedly be difficult to quantitate.

Reasons for these significant facts are not immediately apparent, but there is little doubt that further studies relating to coronary artery disease and physical and psychological factors, the effect of physical activity on coronary circulation, other occupational and social factors, nutritional factors (including obesity), and constitutional factors are clearly indicated.

In the United States, while such complete studies are not available, a survey of death rates by occupation performed in the predepression era (based on data of the United States census of 1930) revealed that farmers and agricultural workers, as a group, had the lowest mortality, followed next in incidence by the executive socioeconomic group. Confirmation of this for the executive group was afforded by a report of the joint committee on mortality presented in the 1949 *Transactions of the Society of Actuaries,* which indicated that the executive group (those carrying large life-insurance policies) did not have an increased mortality as compared to persons insured for small amounts. Such evidence should be borne in mind in evaluating a statement appearing in a *Fortune* magazine article—"The number of executives nipped in mid-career seems to be rising, and the frequency with which 'heart failure' is cited gives this the status of an occupational disease"—as well as when reading obituaries of prominent industrial figures in the morning newspapers.

Work Capacity Evaluation Methods

While there are many groups throughout the country actively interested in the evaluation of cardiac patients for work, there is, as yet, no single definitive test which would assess the work capacity of such patients. In general, it can be safely stated that the demands of stresses of work on the individual person accrue from the physical and emotional demands of work plus the stress imposed by the environmental conditions under which the work is performed. The physical, emotional, and environmental stresses are additive, and real progress has been made by work physiologists in several countries in the areas of physical and environmental influences; however, it is not yet known how to quantify emotional stress.

The physical demands can be roughly estimated by measuring the reaction of a person to a specific job. Cardiac rate, blood pressure, respiratory rate, oxygen consumption, blood lactic acid level, body temperature, and electrocardiographic changes during work and recovery have been measured but some question has been raised as to the validity of such measurements for estimating work capacity.

In general, it can be stated that, other variables being equal, the compensated cardiac patient does not significantly vary from the normal subject, providing his cardiac reserve is not exceeded. It should be of interest to note that in American industry today most workers are expending energy at a rate of 3 to 4 calories per minute, or fewer, with the notable exceptions of foundry workers, longshoremen, and lumberjacks. This is an extremely low level of energy expenditure and is far below that used in various recreational activities, including walking.

A recent tool which has been utilized in such studies is the Lauru force plate. This device measures the physical demands of work which may be below those causing changes in oxygen consumption above the resting level. Cardiac catheterization has also been utilized to measure differences in blood pressure, blood flow, and cardiac work in response to certain levels of physical work, emotional stress, and environmental stress in laboratory studies. This method is quite sophisticated, however, and does not lend itself to making measurements "on the job."

The demands of work can be estimated without making any direct measurements on the individual patient. The metabolic cost of all component movements that make up a job can be summated, and the amount of work done can be calculated in terms of foot-pounds or kilogram-meters. With use of a variety of physiological techniques, numerous studies in many countries have been reported indicating energy-requirement figures for a multitude of jobs. At first these were for normal subjects but recently data have been evolved for the patient with cardiac disease as well. It should be borne in mind that the value of such data should not be overstressed, since neither psychogenic factors nor the rate and conditions of work apparently enter into consideration. In addition, the individual patient's attitude toward work is extremely difficult to quantitate.

From the laboratory other groups have gone directly to the job situation and, with a wide variety of extremely sophisticated newer electronic metering devices, have been able to study the patient actually at work. In conjunction with such highly refined methods, careful cardiologic examination and social and job analyses have been used in the ever-increasing numbers of work classification units that have been established in many communities throughout the United States. Studies have indicated that assessment must consider not only average energy requirements but also peak loads. Generally speaking, most intolerable jobs are such because of the peak loads, whether they last for only a few minutes or a half-hour. Most workers in American industry coast along at low energy-expenditure levels for the bulk of every day. In addition to the direct energy costs of the job, it is also necessary to be aware of many aspects of the patient's life, such as the pace at which he works, his attitude, and the attitudes of those with whom he works. Furthermore, consideration must also be given to his home and marital life and problems relating to transportation to and from the job.

The use of certain laboratory tests, in an attempt to derive a satisfactory test for cardiac function, while indicating certain differences between cardiac patients and noncardiac subjects, has not been a satisfactory technique for measuring the response of the patient to actual on-the-job conditions. Numerical fitness indexes, while adding greatly to knowledge of cardiovascular dynamics, have not been accepted as yardsticks for job placement, especially at low energy-expenditure levels. Preexercise ballistocardiograms also were found not to be of value in this connection.

There is ample evidence to date that, with proper job placement and satisfactory mental and emotional states, the prognosis of the worker with cardiac disease who returns to productive employment is equal to, or better than, that of the worker who ceases work immediately on diagnosis or recognition of his cardiac disability. Long term follow-up studies made in a number of industries have revealed a favorable experience regarding efficiency, absenteeism, accidents, and the need for special job modifications.

Summary

It would appear that, except for the general medical practitioner, the old adage, "Hard work never killed anybody," seems to have some objective basis in fact. Patients with cardiac disease, when selectively placed in industry, can perform creditably.

EMBOLECTOMY IN ARTERIES TO EXTREMITIES

Lester Blum, M.D.
and
Irving Rosenthal, M.D., New York

Forty-eight embolectomies were performed in 38 patients selected for operation by the authors, depending largely on the status of epicritic sensation in the affected extremities. Little diagnostic or therapeutic help was obtained from sympathetic block procedures. Where epicritic sensation was normal or absent only in the metacarpus or metatarsus, a conservative regimen was followed. The operative procedure always included a complete flushing out of all clotted material from the distal arterial tree. Of 43 extremities saved out of the 53 extremities in jeopardy, half were arteriosclerotic and half rheumatic; of the 10 extremities lost, 7 were arteriosclerotic. The arteriosclerotic group of patients had more extensive disease, were older, and were generally in poorer condition than the rheumatic group.

Prior to the last decade, embolectomy was considered something of a surgical adventure. Despite the pioneer work of the Swedish school, the procedure frequently was performed only on recognition that conservative treatment had failed.[1] Therefore it is not surprising that an unhappy result was accepted philosophically. Another deterrent was the popularity of treatment with papaverine, the various sympathetic block techniques, and the anticoagulants. Since the general condition of patients suffering from arterial emboli is usually poor and the underlying heart disease chronic in nature, the adherence to a conservative attitude is quite understandable. Consequently much of the pertinent literature consisted of isolated reports of successful operations.

In the last decade, the remarkable technical improvements of vascular surgery have changed all this so that embolectomy, when timely, has become a procedure in which success is to be expected and failure explained. Because of the inherent mortality of this group of systemically sick patients, the operative results should be gauged in terms of extremities saved as a direct result of intervention.

We wish to present our personal experience with 48 consecutive embolectomies. Because of our intimate concern with each case we feel that the indications for operation, the intervals between occlusion and operation, the technical problems, and the clinical results can be surveyed with an accuracy not possible in an analysis of alien, charted material.

Indication for Embolectomy

Obviously, the basis of any treatment is the establishment of a diagnosis. The physical signs of acute arterial occlusion in an extremity are too well known to need repetition. The association of arrhythmia and an evident block at an arterial bifurcation constitutes an unmistakable picture. Only one of our patients was eurhythmic, and in only one instance was an error committed in localization of the embolic site.

Only those cases in which the ischemia was constant or progressive under careful observation were selected for operation. The crux of the decision is the status of epicritic sensation in the affected extremity. It has been our experience that complete tissue survival is certain if epicritic sensation remains unimpaired. The recognition by the patient of light touch and pinprick confirms the presence of sufficient oxygen tension in the distal capillaries to maintain the functional integrity of the peripheral nerves. Since nerve cells are more sensitive to oxygen deficiency than those of any other tissue, their continued function warrants the assumption of a satisfactory gas exchange throughout the affected part. There is no laboratory test for the mensuration of blood flow that remotely approaches the specificity of this physical sign. It approaches the infallible in that we have never seen tissue death in the presence of unimpaired epicritic sensation.

The color of the affected part and its temperature are of merely ancillary value in estimation of the collateral response after arterial occlusion. These latter physical signs are influenced by numerous factors, including the personal judgment of the observer. Furthermore, it is well known that marked pallor and coolness are common in the hands and feet of normal people with perfectly adequate blood flow.

The level of epicritic sensation must be carefully ascertained and watched during the short period of intensive observation. Any increase in sensory loss or the persistence of anesthesia of the foot or hand strongly indicates operative intervention, whatever the color or temperature.

Motor activity is of rather dubious value in estimation of ischemia and, in fact, can be quite misleading. This is equally true of muscle-tendon-joint

---

From the surgical services of the Mount Sinai Hospital and the Beekman Downtown Hospital.

deep sensation. In fact, in the early stages of peripheral gangrene, toes and fingers can be actively moved.

In short, embolectomy should be performed because of the likelihood of tissue necrosis or severe, crippling functional loss. In no instance of normal epicritic sensation was operation undertaken.

We are puzzled by statements to the effect that it is difficult to recognize and localize peripheral arterial emboli.[2] With the possible exception of oscillometry, any type of instrumentation is quite superfluous.

In view of the better collateral response characteristic of the superior extremity, it is not surprising that in this consecutive series there were only 3 brachial embolectomies as against 45 in the lower extremity.

One facet of our experience is worthy of mention, since it is quite at variance with the prevailing opinion. We derived little prognostic or therapeutic help from the use of sympathetic block procedures such as the paravertebral injection of procaine into the lumbar region or the infiltration of the stellate ganglion. On the contrary, it is our opinion that valuable time is wasted and that extremities unnecessarily are placed in jeopardy by almost routine, repetitive performance of these procedures.

Finally, many of these patients are in poor condition and all are chronically ill. The general state of their health is not considered a contraindication to necessary embolectomy. In this group a gangrenous extremity is an invariably fatal complication.

Timing of Operation

It is evident that the shorter the time lapse between lodgment of the embolus and restoration of the circulation, the better the result. The old concept of the six-hour or eight-hour deadline should be abandoned. It appears to be based on collective data.[3] We were able to save one extremity, although with permanent drop foot and some loss of muscle tissue, despite a lapse of 26 hours between occlusion and clearance of the arterial tree. Similar reports appear in the literature.[4]

In our series the mean time interval in cases with extremity survival is 12.1 hours±1.6; that for extremities lost is 14.1 hours±2.9. Since the standard deviation of the difference is 3.4, it follows that no statistical significance attaches to the difference in time interval between the good and poor results in this particular series. In short, the majority of patients presented themselves within a reasonable time. This offers the analytic advantage of allowing recognition of those other factors which usually assume secondary importance when wide variations in time interval dominate the picture.

Although operation should not be denied up to 24 hours, it is doubtful that complete success is attainable thereafter. In one of our patients, embolectomy 24 hours after occlusion resulted in the restoration of peripheral pulses and a warm foot of good color. However, progressive, aseptic, ischemic muscle necrosis led to thigh amputation 10 weeks later.

Operative Technique

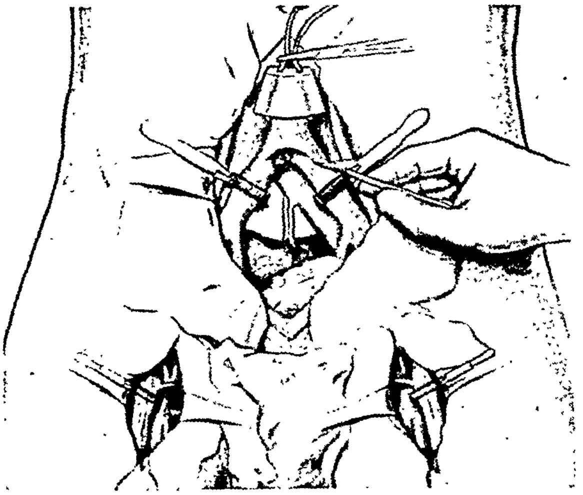
The term "embolectomy" is applied to the procedure of clearing embolic and thrombotic material from the arterial tree of an extremity, regardless of the number of necessary arteriotomies. The affected extremity is completely prepared and draped off, including the digits. In the arm, this includes the axilla, neck, and hemithorax. In the lower extremity, the abdomen is included up to the costal margin for one side and to the nipples in the event of an aortic embolus. This permits examination of the distal portions of the extremities so that the operator himself can palpate for peripheral pulses without unsterilizing the field.

It is preferable to remove aortic emboli by laparotomy and direct aortotomy. This method was used by Bauer[5] in 1913 in the first successful removal of an aortic embolus. A variation of this approach has been described by Linton,[6] who incises the right common iliac artery and milks the clot out while occluding the aorta and the other iliac vessels with modified Bethune tourniquets. Murray[7] has advocated use of the retroperitoneal abdominal approach and incision of the right common iliac artery.

Since the condition of patients suffering from lodgment of an embolus at the aortic bifurcation frequently is poor, an indirect approach has much logical appeal. Credit for the first use of catheters, suction, and irrigation in the dislodgment of emboli through distally placed arteriotomies must go to Handley,[8] who, in 1907, failed to completely remove an iliac embolus with propagated clot, despite a valiant effort. In his desire to do a complete arterial toilet, he opened the popliteal artery as well and passed through it fine catheters in an attempt to clear the channel well down the extremity. We feel that the proximal passage of instruments through femoral or iliac arteriotomies in an attempt to clear the aortic bifurcation is not a wise move nor usually an effective one. The danger of pushing thrombotic material into the blood stream of the opposite extremity is real.

In our operative plan, the femoral arteries are first exposed and serrefines applied to prevent material being swept down (see figure). Then laparotomy is performed, the retroperitoneum exposed, and the aortic bifurcation isolated by passage of rubber catheters above as well as below the iliac vessels. With the blood flow thus controlled, a curved incision is made in the concavity of the bifurcation.[9] Through this opening almost all the clotted material can be removed easily. After suture of the aortotomy wound, the taut catheters are released and the blood stream thus is released. Short transverse arteriotomies then are made cephalad to the femoral serrefines. This allows flushing out of smaller particles. After these transverse arteriotomies are sutured all clamps are removed, the abdomen is closed, and the extremities are carefully examined on the table. If there is any doubt as to the completeness of the procedure, the patient is turned and the popliteal artery on that side is exposed. If pulsating toward and including its division, the wound of exposure promptly is closed; if not, a transverse incision is made in the popliteal artery and blood flow established.

Since femoral and iliac emboli constitute the majority of cases, the operative procedure easily can be formalized into a fairly constant technical ritual. The initial step is exposure of the common femoral artery and its divisions, the deep and superficial femoral vessels. If the embolus is lodged at this site, a short transverse opening in the common femoral artery just at the origin of the two divisions is made so that the distal clot can be irrigated and sucked from both the superficial and deep femoral vessels. After this the embolus can be gently extracted and the arteriotomy wound closed. In the case of an iliac embolus, the inguinal ligament is divided and the exposure cleared cephalad to the necessary level. If essential, further transverse arteriotomies can be made. With the restoration of a good pulsation at the femoral level, the operation is completed only by making certain that there is no distal occlusion.



Exposure of femoral arteries and application of serrefines before exposure of aorta for removal of embolus at bifurcation.

In the absence of indisputable pedal pulses, it is our routine to turn the patient over and expose the popliteal artery. If this vessel is not actively pulsating, the procedure must be carried on until it is.

We do not advocate opening the posterior tibial artery at the ankle.[10] In addition to the disadvantage of so distal an incision in an extremity subjected to severe vascular insult, we have not experienced tissue loss in the presence of an actively pulsating popliteal artery down to, and including, its division into the tibial vessels.

There are three technical points in the performance of embolectomy which are worthy of emphasis: 1. Arteriotomies should be placed transversely. This is of great help in diseased vessels, since it permits easier exposure than the commonly employed sagittal incision and can be closed more readily. Furthermore, there is little constriction of the lumen. 2. Completeness of the arterial toilet means the difference between success and failure. It is essential to flush out all clotted material as far down the extremity as possible. This may prove tedious but it is basic. 3. The procedure of embolectomy in an extremity is not properly concluded unless the pedal pulses are unequivocally present or the exposed popliteal artery is pulsating down to, and including, its bifurcation.

Clinical Data

Our personal experience is composed of the 48 consecutive embolectomies about which data are presented in table 1. Since 5 of the emboli were aortic, 53 extremities were in jeopardy. Of these, 10 were lost, 5 through amputation and 5 through ischemia at the death of the patient. There were 14 iliac emboli, 18 femoral, 8 popliteal, and 3 brachial. This distribution (tables 1 and 2) resembles that reported by others.[11]

The paucity of upper extremity procedures is not surprising, since this is a less common site for lodgment and surgery is required less often because of the remarkable recuperative power of this extremity after vascular occlusion, in sharp contrast to the inferior limb. This can be ascribed to the profusion of collateral blood vessels about the elbow, to the lesser blood flow demand of the smaller muscle mass of the arm, and to the relative freedom of the upper extremity vasculature from arteriosclerosis. In fact, we performed embolectomy in the arm only after prolonged observation and an established certainty that matters were not responding to a conservative regimen. In one case, brachial exploration was undertaken after 50 hours of observation and with a good result.

The 48 operations were carried out on 38 patients; 17 of the patients died postoperatively. This approximates the usually reported mortality of 50% in this category of patient. The chief cause of death was heart failure, with cerebral embolism second and shock third (table 2). Since these patients are desperately sick, the success of the procedure should be measured in terms of extremities saved that otherwise would be unequivocally lost.

It is difficult to understand how authors can compare the operative and conservative methods of treating peripheral embolism in terms of mortality and extremity salvage. In the first place, the patient deaths are not related *ipso facto* to the performance of the operation. Second, if patients are carefully selected for exploration on the basis set forth above, the results of conservative care must necessarily be better than in the operative group, since the latter includes only those patients definitely in danger of losing limb and, possibly, life.

Since the interval between lodgment of the embolus and restoration of blood flow was not significantly different in patients with good and bad results in our series, and since the identical technique was followed throughout, it is possible to evaluate the factor of pathogenesis (table 1). Of 43 extremities saved, half were arteriosclerotic and the other half rheumatic. However, of the 10 extremities lost, 7 were arteriosclerotic. Not only are these patients older and in poorer condition than those in the rheumatic group, but in them the arterial tree is extensively diseased. As mentioned previously, this

TABLE 1.—*Results of Forty-eight Consecutive Embolectomies in Thirty-eight Patients*

Patient, No.	Age, Yr.	Site	Time Lapse Between Lodgment and Removal of Embolus, Hr.	Pathogenesis	Results	Remarks
1	58	Aortic	9	Rheumatic	Good, l. Good, r.	Postoperative fecal fistula; died 7th day, congestive heart failure
2	48	Aortic	4	Rheumatic	Good, l. Good, r.	Discharged after 56 days
3	56	Aortic	6	Rheumatic	Good, l. Good, r.	Died within 48 hr., congestive heart failure
4	52	Aortic	6	Rheumatic	Good, l. Good, r.	Occurred 9 days after commissurotomy
5	38	Aortic	6	Rheumatic	Good, l. Good, r.	Discharged after 11 days
6	57	Iliac	9	Arteriosclerotic	Good	Discharged after 33 days
7	36	Iliac, l. Iliac, r.	5	Rheumatic	Bad Bad	11th day left thigh amputation; right leg ischemic; died after 32 days, cerebral embolus
8	57	Iliac, l. Iliac, r.	9	Rheumatic	Good Good	Died in operating room in shock; post mortem examination showed patent arteries
9	46	Iliac, l. Popliteal, r.	25	Rheumatic	Bad Good	11th day left thigh amputation; frequent subsequent mitral valvulotomy
10	70	Iliac, r. Femoral, l. Femoral, l. (8 days later)	5	Arteriosclerotic	Good Good Good	Died within 29 days postoperatively, septicemia; also had visceral emboli
11	55	Iliac	6	Arteriosclerotic	Good	Discharged after 24 days; well 2 yr. later
12	53	Iliac, l. Iliac, r.	10	Arteriosclerotic	Good Bad	Sudden death in wheel chair, 4th day
13	52	Iliac, l. Popliteal, r.	9	Arteriosclerotic	Good Good	Sudden death 3rd day, coronary thrombosis
14	70	Iliac, l. Iliac, r.	12	Arteriosclerotic	Good Bad	Died in shock, 10 hr. postoperatively, aortoiliac thrombosis
15	80	Iliac	16	Arteriosclerotic	Good	Sudden death within 24 hr.
16	38	Femoral, l. Femoral, r.	7	Rheumatic	Good Good	Died, 18 days postoperatively, cerebral embolus
17	51	Femoral	8	Rheumatic	Good	Died in operating room, cerebral embolus
18	76	Femoral	8	Arteriosclerotic	Bad	Died within 10 days, congestive heart failure
19	48	Femoral	7	Rheumatic	Good	Subsequent mitral disease
20	40	Femoral	20	Rheumatic	Good	Discharged within 48 days
21	67	Femoral, l. Femoral, r.	25	Arteriosclerotic	Bad Good	Left leg amputation, 6 days postoperatively; died within 7 hr.
22	63	Femoral	6	Arteriosclerotic	Good	Discharged after 32 days
23	60	Femoral	12	Arteriosclerotic	Good	Discharged after 18 days
24	71	Femoral	17	Arteriosclerotic	Good	Sudden death within 14 hr.
25	44	Femoral	5	Rheumatic	Good	Discharged after 11 days; slight drop foot
26	61	Femoral	30	Arteriosclerotic	Bad	Pulses restored but muscle necrosis necessitated amputation, 10 wk. postoperatively
27	60	Femoral	6	Arteriosclerotic	Good	Discharged after 21 days; well 1 yr. later
28	60	Femoral	3	Neoplastic	Good	Discharged after 14 days; died after 2 mo., lung cancer
29	61	Femoral	16	Arteriosclerotic	Good	Well 1 mo. later
30	63	Popliteal	24	Arteriosclerotic	Good	Discharged after 27 days
31	73	Popliteal	8	Arteriosclerotic	Bad	Thigh amputation; discharged after 24 days
32	69	Popliteal	12	Arteriosclerotic	Good	Died 2nd day, pulmonary embolus
33	69	Popliteal	17	Arteriosclerotic	Good	Died 8th day, coronary thrombosis
34	39	Popliteal	15	Rheumatic	Good	Subsequent mitral disease
35	63	Popliteal	3	Arteriosclerotic	Good	Discharged after 12 days
36	72	Brachial	50	Arteriosclerotic	Good	Discharged after 9 days
37	74	Brachial	12	Arteriosclerotic	Bad	Died 4th day, congestive heart failure; diabetes, severe
38	44	Brachial	10	Rheumatic	Good	Subsequent mitral disease

Of the 48 emboli, 45 presumably originated in the heart, one apparently arose from an aortic atheromatous ulcer, one was a clot from the wall of an aortic aneurysm in process of resection, and one was a neoplastic embolus coming from a carcinomatous lung (table 2).

poses a problem in the mechanics of arteriotomy, vessel exploration, and closure. It is difficult to clear a tenacious clot from tortuous, irregularly narrowed arteries. The final result is threatened also by the greatly diminished collateral potential of the diseased smaller vessels.

Since there was reason to believe that a large number of our patients lacked pedal pulses before embolic occlusion occurred in their larger vessels, we could not establish the restoration of distal pulses as essential for a good result designation. We based our results solely on unequivocal preservation of a functioning extremity without tissue loss or any damage sufficient to cause overt signs of ischemia. In this connection, it should be noted that in one patient, operated on 24 hours after occlusion, peripheral pulses were restored and there was no loss of integument. However, after 10 weeks it was necessary to perform a thigh amputation because of progressive aseptic muscle necrosis resulting from the initial period of ischemia.

Table 2.—*Analysis of Forty-eight Consecutive Embolectomies in Thirty-eight Patients*

Type of Embolus	No.	Extremities in Jeopardy	No.
Aortic	5	Saved	43
Iliac	14	Lost	10
Femoral	18	Amputated	5
Popliteal	8	Ischemia (at death)	5
Brachial	3		
Origin of Embolus	**No.**	**Postoperative Deaths**	**No**
Heart	45	Heart failure	10
Aortic atheroma	1	Cerebral embolus	3
Aortic aneurysm	1	Shock	2
Lung neoplasm	1	Septicemia	1
		Pulmonary embolus	1

Analysis of Bad Results

As previously noted, there was no significant difference between the group of 43 salvaged extremities and the 10 bad results with regard to elapsed time between lodgment of the embolus and restoration of blood flow. The average ages of both groups also were identical (table 1).

The only significant contrast was in pathogenesis. Only 3 of the 10 lost extremities occurred in patients with rheumatic disease. Furthermore, technically two of these were not handled as well as the remainder and the third followed a time interval of 25 hours and an incomplete procedure. The remaining seven bad results were all arteriosclerotic in origin. This is in sharp contrast to the equal incidence of rheumatic and arteriosclerotic disease in the salvaged group (table 1).

It is quite possible that the systemic and local factors accounting for this loss of limb will always remain insurmountable. The disseminated nature of atheromatous disease throughout the vasculature of the extremity and the precarious state of the tissues preceding the added insult of embolization are weighty factors in the balance against success. Even the mechanical restoration of blood flow in diseased major arteries is made difficult by filling of the irregularly constricted passages by tenacious clot.

Incision, exploration, and arteriotomy closure of a diseased vessel can become a complicated, tedious affair, threatening successful completion of an embolectomy. The intima strips, the media fragments, and the sutures do not hold, because the brittle vessel wall is cut through by the silk thread. There can be little doubt that, next to the time interval, the condition of the peripheral vasculature is the most important single factor in determining the success of embolectomy.

Summary

Forty-eight consecutive embolectomies performed by us were subjected to analysis. Aside from the time interval between lodgment of the embolus and reestablishment of blood flow, the most significant factor determining success was the condition of the vasculature of the affected limb. The chief cause of failure was arteriosclerotic change in the blood vessels. The selection of patients with embolism for operation definitely can be made on the basis of physical examination. The absence or presence of epicritic sensation is the most important physical finding. The use of sympathetic block procedures and vasodilator drugs was of little help. In fact, this practice leads to confusion and delays necessary operation.

Where properly indicated, timely embolectomy is a limb-salvaging and life-saving procedure in which success is to be expected and failure explained.

101 E. 93rd St. (28) (Dr. Blum).

ARTERIAL EMBOLECTOMY

Seebert J. Goldowsky, M.D.
and
J. Robert Bowen, M.D., Providence, R. I.

The late results of arterial embolectomy have been assessed after 46 operations performed on 42 patients over a period of 11 years. The ages of the patients ranged from 38 to 82 years. There were 17 hospital deaths. Among the survivors there was 100% salvage of the imperiled extremities. Since every patient in this series was followed up successfully, complete attrition data were obtained, the survival rate declining progressively to 40% for 5 years and 27% for 11 years. When the operation was delayed eight hours or more after the onset of symptoms the mortality was but little higher than that after immediate operation. The data did not answer the question of whether anticoagulant therapy was preferable to surgery in this situation.

Since the first successful performance of embolectomy by the Frenchman Labey[1] in 1911, this procedure has gained, with but few dissenting voices, general acceptance as the treatment of choice in the management of peripheral arterial embolism. Among the dissenters is Wessler,[2] an advocate of early anticoagulation therapy with heparin sodium. He has concluded that embolectomy cannot be recommended as the treatment of choice in acute occlusive disease because of the high mortality associated with this procedure. A generation ago (in 1923) Key[3] reported 6 successful embolectomies in 10 attempts. This remarkable experience compares favorably with recently reported series. The most important contributions of the past 20 years have been concerned with the application of more modern and handier equipment and the availability of effective anticoagulants for local and systemic use. It is of interest that the now popular retrograde flushing procedure was described as long ago as 1930 by Lerman and associates.[4]

Purpose of Study

Larger series[5] than the one here reported can be found in the literature, some with better results, perhaps. However, after adequate search, we have failed to find a single follow-up study in any one significant series. We were curious to know the ultimate fate of patients subjected to embolectomy. Lack of any pertinent useful information led to this review of our experience. Since we have been successful in attaining a 100% follow-up, we felt it would be of value to make this material a matter of record. Furthermore, it seems worthwhile to appraise an experience with this operation in a non-university center.

Embolectomy

The study here reported is based on 46 operations performed on 42 patients over a period of 11 years, up to Jan. 1, 1959. All but one of the procedures were carried out at Rhode Island Hospital. Thirteen of these embolectomies on 12 patients were performed by one of us (S. J. G.). A small additional number of operations described as embolectomy was excluded from the study because of the difficulty of differentiating between arteriosclerotic thrombosis and true embolism on clinical or pathological grounds. In general, these latter patients, having extensive thrombosis of several days' duration, could not be classified as having acute embolic occlusion.

Population.—The patients studied included 24 women and 18 men. Their ages at the time of the first intervention ranged from 38 to 82 years, with an average age of 62.3 years. Table 1, which gives these patients' ages by decades, shows that more than one-half of the cases of acute embolic occlusion occurred in patients within the two decades from 60 to 79 years of age. The average age of 14 patients with rheumatic heart disease was 53.8 years, while that of the others was 66.5 years. In 9 of the latter 28 patients there was cardiac pathology based on coronary occlusion. Twenty-six of the total group of 42 patients had auricular fibrillation.

Limb Salvage.—Seventeen hospital deaths resulted from 46 operations, i. e., an operative mortality of 37%. There was no loss of limb among the

Read at the Annual Research Day, Rhode Island Hospital, April 18, 1959.

survivors. This would give a limb survival equal to the patient survival, or 63%. Among those who died, three patients had had actual amputations and four inevitable gangrene. This would provide a potential limb salvage (in 47 opportunities comprising 46 operations, and one bilateral procedure) of 85.1%.

If the above results are broken down for the periods from 1948 to 1953 inclusive and 1954 and 1958 inclusive, 18 operations were done in the first and 28 in the second period. The mortality in the first period was 33.3% (6 patients), while in the second it was 39.2% (11 patients). Evaluation of limb salvage within the same periods and with use of the figure of 47 opportunities, as indicated above, shows 2 actual or inevitable amputations out of 19 opportunities in the first and 5 out of 28 in the second group. This would yield an actual or potential limb salvage of 89.5% for the first and 82.1% for the second period. If we had elected to count each of the five aortic cases as two opportunities instead of one, the calculated potential limb salvage would have been slightly better. These small numbers do not yield statistically significant differences, but it is fair to say that there has been no obvious improvement in mortality or limb salvage. This may be accounted for in part by a more aggressive approach in late or very severe cases during the second period.

TABLE 2.—*Effect of Delay on Operative Mortality in Forty-six Embolectomies*

Time from Symptoms to Surgery, Hr.	No. of Operations	No. of Deaths	Mortality
0- 4	13	4	
4½- 8	15	6	
8½-12	10	2	
12½-18	4	3	
18½-24	2	1	
>24	2	1	
0- 8	28	12	35.7%
> 8	18	18	38.9%

Signs, Symptoms, and Pathology.—In the 46 operations reported here, 49 emboli were found in our 42 patients, of whom 2 had multiple emboli (two in each instance) and one a bilateral embolus. The majority of emboli were located in the femoral system (17 in the common femoral and 12 in the superficial femoral arteries and Hunter's canal), 5 in the aorta, 6 in the popliteal, and 4 in the axillary and brachial arteries. Since only two of the five operations on aortic emboli were successful, the mortality for this small group was 60%. A total of 13 retrograde flushing procedures were performed, the first in 1955.

TABLE 3.—*Survival After Embolectomy*

	Yr. of First Operation											Total No. of Patients
	1948	1949	1950	1951	1952	1953	1954	1955	1956	1957	1958	
No. of 1st operations	1	2	2	3	2	5	2	1	4	9	11	42
Length of survival yr.	10-11	9-10	8-9	7-8	6-7	5-6	4-5	3-4	2-3	1-2	>1	
Living at time of writing		1	1	1		1			2	5	5	16
Dead at time of writing					1	1		2	2		20	26

Table 2 analyzes the effect of the time interval from onset of symptoms to surgery. Twenty-eight of the 46 operations were performed within eight hours of onset of symptoms, while in 18 cases the time exceeded eight hours, ranging up to five days. It will be seen that the operative mortality in the first group was 35.7%, while in the second it was increased slightly to 38.9%.

In 35 of our 42 patients the heart was presumed to be the source of the emboli. However, this was verified in only five instances, four at postmortem examination and one at the time of a subsequent mitral valvuloplasty. In one case of mitral valvuloplasty no thrombus was found. In seven cases no source or origin for the emboli could be postulated on the basis of clinical evidence, and in five of these none could be demonstrated even at postmortem examinations, which included careful inspection of the aorta.

Follow-up Studies

Survival Rate.—The number of cases out of the total of 42 available for follow-up at varying periods are shown in table 3. Of the 22 patients who had had their first operation more than two years ago, 12 (54.5%) survived two years or more. Of the 18 patients operated on more than three years ago, 8 (44.4%) survived three years or longer. Of the 15 patients operated on more than five years ago, 6 (40.0%) survived five years or longer. Sixteen (38.1%) of the total of 42 patients were still alive at the shut-off date. However, 5 of these 16 were operated on during the last year. In other words, of the 31 patients first operated on more than one year ago, only 11 (35.5%) were still alive at the close of this study, and of the 22 patients operated on more than two years ago, only 6 (27.3%) were alive as of the same date. Thus it appears that, although the chances of surviving an initial embolectomy exceed 60% (26 out of 42, or 61.9%), the survival rate declines progressively to 40% for five years, with a continuing, progressive decline thereafter.

Long-term Anticoagulant Therapy.—Our experience with long-term anticoagulant therapy has been appreciable and fairly satisfactory. Twelve of our 42 patients eventually were placed on long-term therapy, usually with bishydroxycoumarin (Dicoumarol). These patients have been undergoing treatment for periods ranging from seven and one-half months to seven and one-half years (table 4). Nine of these 12 patients, including one treated for seven and one-half years, are still living; each of two minor and one major embolic episodes which occurred among them was due to temporary lack of control. The three deaths among the 12 patients receiving anticoagulant therapy were due, respectively, to coronary occlusion, retroperitoneal hemorrhage after sympathectomy, and inanition 16 months after an extensive resection of the small intestine for embolic infarction. Thus, none of the deaths in this group was attributable directly to a major embolus, and only one patient required a subsequent embolectomy. Neither of two patients on whom a mitral valvuloplasty had been performed has had further embolic episodes.

Sequelae.—Of the 42 patients in our series, 2 had two and one patient three separate embolectomies. So far as can be determined from their histories, 16 patients had had previous nonsurgical embolic episodes of all types, 11 having had two episodes. Subsequent related surgical procedures were as follows: lumbar sympathectomy, four; thigh amputation, three; mitral valvuloplasty, two; repair of evisceration after aortic or iliac exploration, two; and one each of extensive jejunal resection for mesenteric embolism, exploration without resection for extensive inoperable mesenteric embolism, and fasciotomy for muscle edema and ischemia. Two patients had drop foot from ischemic neuritis. Muscle function eventually returned in one of these; no information is available on this point for the other. Restoration of peripheral pulses was not uniformly accomplished. Satisfactory, late clinical results as regards adequate peripheral circulation were generally obtained, however, despite failure of peripheral pulses to return. Late ischemic sequelae presented a serious problem in only one case in this series.

The causes of death in the 17 postoperative fatalities and in the 9 late deaths are listed in tables 5 and 6.

Summary and Conclusions

Our follow-up study on 42 patients who had been subjected to 46 peripheral arterial embolectomies resulted in the following findings: 1. The over-all operative mortality for peripheral arterial embolectomy was 37%. 2. The chances of surviving the first embolectomy were 61.9%. 3. The chances of surviving the first embolectomy and living three years or longer were 44.4%. 4. The chances of surviving the first embolectomy and living five years or longer were 40%. 5. The attrition continued significantly after the five-year period. Of all patients operated on more than two years ago, but within the 11 years of this study, only 27.3% still survive. 6. Initial high mortality is a serious problem. Limb salvage, on the other hand, is satisfactory. The nature of the disease in these very ill patients is the most important factor contributing to this mortality and to the continued attrition thereafter. 7. Late peripheral circulatory sequelae have not, for the most part, been a serious problem. 8. Long-term anticoagulation therapy has been found to be a valuable prophylactic procedure against further emboli. It is indicated in auricular fibrillation as well as in occasional cases of persistent mural thrombus with recurrent embolus after myocardial infarction. Atrial appendectomy, although resorted to only twice in this series, undoubtedly has a place in properly selected cases of rheumatic valvular disease. 9. Delay in instituting surgery was less of a factor in mortality than we

had anticipated. Inevitably it must, however, affect both limb salvage and mortality to some extent. 10. This study neither clearly supports nor unequivocally refutes Wessler's contention that anticoagulation therapy with heparin rather than surgery is the treatment of choice in acute arterial embolism. Our experience would indicate, however, that his conclusions may have validity in patients who are poor surgical risks.

ACUTE ATTACKS OF GOUT PRECIPITATED BY CHLOROTHIAZIDE-INDUCED DIURESIS

Leon J. Warshaw, M.D., New York

Side-effects due to chlorothiazide, an orally administered diuretic, have been infrequent, and the difficulties incurred have not been serious. Increased potassium excretion causes hypopotassemia in patients who have taken the drug continuously for long periods of time, but this can usually be countered by adding supplementary potassium compounds to the patient's diet. Chlorothiazide has also produced hyperuricemia and, in patients with a gouty diathesis, has precipitated acute attacks of gouty arthritis. Two such cases are reported. The presence of gouty arthritis should be suspected in patients treated with chlorothiazide or one of the other benzothiadiazine compounds and who complain of aching joints and, especially, of painful feet. Stopping the administration of the drug usually suffices to control the arthritis, but, when arthritis is severe, use of colchicine may be necessary.

Chlorothiazide has recently become popular as an orally administered diuretic and has been used in the treatment of essential hypertension to enhance the effects of specific hypotensive agents. Although earlier claims of its diuretic potency on oral administration being superior to that of intramuscularly injected meralluride sodium have not been substantiated,[1] it has proved to be a reasonably effective oral diuretic both in the treatment of congestive heart failure and in maintenance of cardiac compensation once it has been restored.[2] The freedom of its use, with doses being given daily and twice daily, without interruption over long periods of time, has probably been more responsible than its allegedly superior potency for many of its triumphs as a diuretic.

Untoward effects after its use have, at least thus far, appeared relatively infrequently. Except for the tendency toward hypopotassemia, which can be controlled by the prophylactic administration of supplementary potassium compounds, these have not appeared to be consequential.[2] Recently, however, cases of gout apparently precipitated by chlorothiazide-induced diuresis have been observed. Because of the implications of this type of reaction, with regard to the long-continued use of chlorothiazide and the othe [illegible] derivatives that have since been introduced, it appeared desirable to report two of these cases in detail.

Report of Cases

Case 1.—A 40-year-old man had been under treatment for a postphlebitic syndrome of the right [illegible] the residue of two classic attacks of acute

---

From the Cardiovascular Research Unit, Beth Israel Hospital.

thrombophlebitis. The first had occurred three years earlier as a complication of acute erysipeloid cellulitis of the upper part of the thigh. The second attack followed in a little less than a year and was associated with cellulitis of the foot complicating an acute flare-up of long-standing dermatophytosis. Except for the generalized aching that accompanied the acute febrile illness, he denied any symptoms suggestive of arthralgia or arthritis. Urologic investigation of an episode of painless gross hematuria during his first attack of phlebitis (attributed to anticoagulant therapy, despite blood prothrombin times well within the usual therapeutic range) revealed no evidence of renal disease. The serum uric acid level was normal at that time.

The rest of the history was essentially noncontributory except that it indicated a persistent tendency toward overweight. About once every two years, the patient would partake of a high-protein, low-calorie diet featuring at least two servings of beefsteak daily. On this regimen he would lose weight at an average rate of about 2 to 4 lb. (0.9 to 1.8 kg.) per week and would usually maintain it until a total of about 30 lb. (13.6 kg.) had been lost. On a number of occasions he had also used a proprietary reducing medicament or a dextro amphetamine sulfate preparation prescribed for him by his personal physician. The only difficulty ever associated with these weight-reduction stints was the tendency for the lost pounds gradually to reaccumulate.

After the episodes of phlebitis, this reaccumulation of weight appeared to intensify his postphlebitic syndrome, the symptoms of which were edema of the leg, frequent twinges of pain along the veins reminiscent of the pain experienced during the acute phlebitis, and fatigue, both generalized and of the involved extremity.

Sodium restriction and injections of mercurial diuretics had seemed to reduce somewhat the swelling and discomfort in the leg at the time of the acute phlebitis. Chlorothiazide, which had since become available, was substituted for the mercurial diuretic therapy; the dose was 1.0 Gm. twice a day by mouth. The first few doses appeared to produce satisfactory diuresis, a loss of 4 lb. (1.8 kg.) being recorded after 24 hours (fig. 1).

On the third day therapy was interrupted by the acute onset of fever, malaise, pain, tenderness, and signs of acute inflammation involving the entire dorsum of the right foot and the ankle. Although far from similar in appearance, this was attributed to a flare-up of the cellulitis of that foot from which the patient had apparently recovered several months earlier. A broad-spectrum antibiotic was prescribed and he was instructed to "force" fluids. When 0.6 Gm. of aspirin every three or four hours failed to relieve his discomfort, codeine was prescribed. The symptoms and signs diminished at a satisfactory rate; he was afebrile in 48 hours and seemed completely recovered after five days.

Several months later, having abandoned this reducing attempt because of the acute symptoms, he resumed the diet, salt restriction, and the doses of chlorothiazide described above. Once again, diuresis resulted. It was followed two days later by a return of the fever, malaise, and a similar inflammatory involvement. This time, however, the latter involved both ankles and the region of the right first metatarsophalangeal joint and appeared much less like cellulitis than like an acute attack of gout. The serum uric acid level was 6.2 mg.%. A course of colchicine therapy (0.5 mg. every hour for eight doses) produced prompt improvement. Within 24 hours, he was afebrile and the inflammatory signs and symptoms had largely subsided. He was given doses of probenecid regularly, and one week later the serum uric acid level had fallen to 3.7 mg.%.

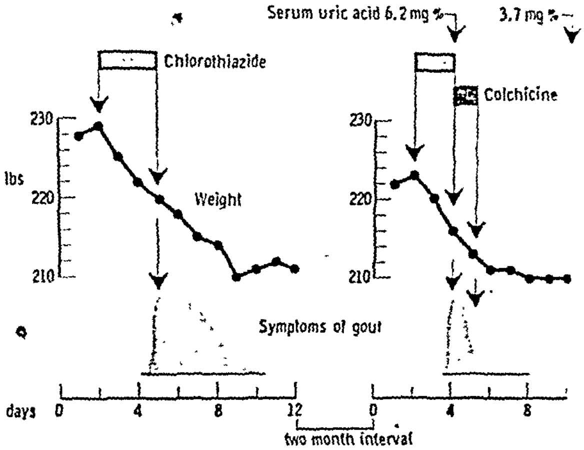

Fig. 1 (case 1).—Data obtained during two episodes of gout precipitated by chlorothiazide (dose, 2 Gm. per day) in 40-year-old man with postphlebitic syndrome and obesity.

Probenecid therapy has been maintained to the time of this writing, and there have been no further clinical indications of gout in the little over a year that has elapsed since his last attack. He has refused additional trials of diuretic therapy.

Case 2.—A 48-year-old man with rheumatic mitral and aortic valvular lesions was seen because of moderate congestive heart failure. This was his first experience with this syndrome. Except for the heart disease, the history was essentially negative. Attacks of classic migratory polyarthritis had accompanied his childhood episodes of rheumatic fever, and, since then, he had seemed to be particularly susceptible to vague arthralgias and myalgias. These were induced by respiratory infections, physical fatigue, and occasionally by abrupt changes in weather; they were not severe and usually subsided spontaneously or after he took a few doses of aspirin. On at least two occasions, more than 10 years before, these episodes had been more severe and persistent and had featured pain and swelling of the feet. During one such episode, a physician had suggested gout as a diagnosis and had prescribed a colchicine preparation, with excellent results. A special diet had also been prescribed but was abandoned by the patient soon after his recovery.

The congestive failure was treated by a previously described regimen[2] featuring digitalization, sodium restriction, and daily use of a diuretic (chlorothiazide, 1.0 Gm. by mouth). A satisfactory response was noted; the patient lost 13 lb. (5.9 kg.) of extracellular fluid in three days, and the symptoms of his failure were relieved. However, on the third day of diuretic therapy, there was an abrupt onset of fever and typical acute gouty arthritis of the left first metatarsophalangeal joint. The serum uric acid level eight hours after the onset of this syndrome was 5.4 mg.%. Diuretic therapy was interrupted and a course of colchicine was given, with a prompt subsidence of the gout. Probenecid was given (1.0 Gm., then 2.0 daily), and after a week, the serum uric acid level fell to 3.0 mg.%. While the therapy with probenecid was still being continued, intramuscular injections of meralluride sodium, first 1.0 and then 2.0 cc., were given daily. The resultant diuresis, although not as marked as that observed initially, produced an additional loss of 8 lb. (3.6 kg.) and was otherwise without incident (fig. 2).

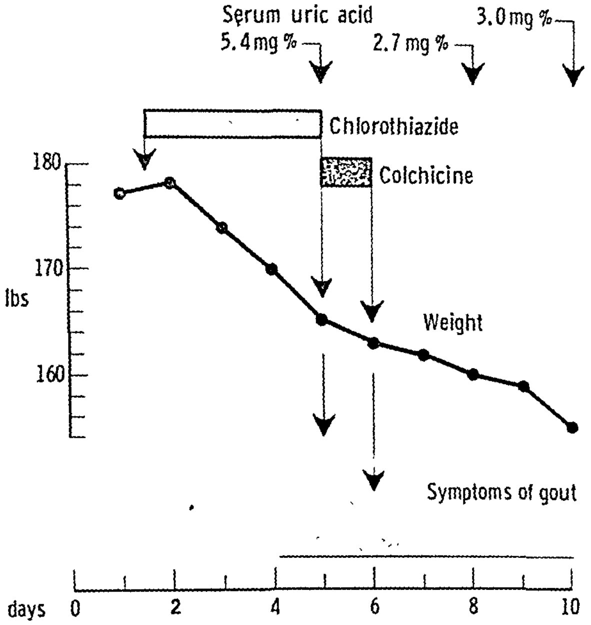

Fig. 2 (case 2).—Data obtained during period of acute gout precipitated by chlorothiazide (dose, 1 Gm. per day) in 48-year-old man with rheumatic heart disease and in moderate congestive failure.

Comment

The occurrence of hyperuricemia in patients receiving chlorothiazide has been reported previously. One case was found in a group of 87 patients with fluid retention treated with chlorothiazide in a clinical study of its effectiveness as a diuretic agent.[2] Since serum uric acid levels had been determined in only a few of the cases at that time, it is probable that there may have been more. Other instances of hyperuricemia were subsequently found among those patients and in others given similar treatment since that time. In their study of the effects of chlorothiazide on electrolyte balance, Laragh and associates[3] found a significant elevation of the serum uric acid level in six of their eight patients, which returned promptly to normal on cessation of chlorothiazide therapy. This occurred without elevation of the urea nitrogen concentration. Although preliminary serum uric acid determinations had not been made, Monroe and colleagues[4] found this value to be significantly elevated in seven of nine patients who had been *receiving chlorothiazide continuously for periods* up to 10 months in duration. The serum uric acid levels tended to fall when the drug was not used for 7 to 10 days and to rise again when its administration was resumed.

Hyperuricemia and gout.—In all of these cases of hyperuricemia associated with chlorothiazide administration, no symptoms were noted and none of the patients were thought to have gout. Recently, however, Oren and associates,[5] who found elevated uric acid levels ranging from 6.3 to 10.0 mg.% in each of a group of 12 patients who had used chlorothiazide for long periods of time, noted that 2 patients complained of joint pains, especially in the feet. In one patient these symptoms appeared about three months after the institution of chlorothiazide therapy, disappeared a few days after it was interrupted, returned two weeks after it was resumed, and disappeared again when use of chlorothiazide was finally abandoned. Their second patient developed painful feet about six months after beginning chlorothiazide therapy, and three months later he was found to have typical physical signs and roentgenographic evidence of gouty arthritis of the right great toe. This patient was subsequently discovered to have had the clinical signs and roentgenographic evidence of gout several years prior to the chlorothiazide therapy. On this occasion, cessation of chlorothiazide therapy was followed by subsidence of all of the signs and symptoms.

Gutman[6] noted the occasional appearance of hyperuricemia due to chlorothiazide therapy and also precipitation of acute gouty arthritis in patients with a history of gout or in whom gout was presumably latent. He remarked that both the hyperuricemia and the acute attacks of gout in gouty subjects occur more regularly after hydrochlorothiazide administration and considered them a serious drawback to the use of this drug.

The mechanism by which chlorothiazide produces hyperuricemia is not known. The studies of Demartini[7] indicated that the prolonged use of this compound interferes with the renal excretion of urates. He believed, as did others who have studied this phenomenon, that explanations on the basis of a presumed increase in the catabolism of nucleic acids are probably not correct. Whether the mechanism is the same as that producing the hyperuricemia of naturally occurring gout is not yet known. Nor has it been established whether this is a purely incidental occurrence or one that is found only in patients with latent gout. The well-known absence of correlation between serum uric acid levels and clinical symptoms in patients with known gout makes it unlikely that a satisfactory answer will be found in the observation of acute articular episodes. The recent report by Kohn and Prozan,[8] suggesting a relationship between hyperuricemia and coronary atherosclerosis with myocardial infarction, makes it urgent that the true significance of the hyperuricemia be established.

Precipitation of Articular Episodes.—The mechanism by which an acute articular episode is precipitated in a gouty patient is also not understood. Some of the various agents held to have caused this phenomenon are acute infections, acute blood loss, prolonged bed rest, surgical operations, emotional trauma, and local x-ray therapy. Various drugs, including penicillin, thiamine chloride, vitamin B_{12}, insulin, liver extract, and ergotamine tartrate, have also been presumed to cause an acute attack.

Probably the first to note the association of acute gout with a diuretic agent was Hench,[9] who merely made a passing allusion to mersalyl sodium (Salyrgan) theophylline as one of the agents capable of activating quiescent gout in a gout-susceptible patient.

Several years later, Price[10] reported five patients with histories of gout in whom an acute attack was immediately preceded by "critical diuresis" produced by a diuretic regimen consisting of injections of mersalyl on alternate days. Although the previous doses had apparently produced adequate diuresis, the attack of gout appeared to be related to the greatest urinary output produced by successive doses of the diuretic. Price called this the "critical diuresis" and compared it to the much less marked spontaneous diuresis frequently observed to precede the acute exacerbations in gouty persons who do not have heart disease. Because all five of his patients died of heart disease within a few weeks to a few months after their attacks of gout, Price considered the mersalyl-induced attack to signify a bad prognosis. This prognostic implication has been challenged by Talbott,[11] who has also observed acute gout after induced diuresis. The latter's view appears to be supported by the cases described by Oren and associates[5] and those reported above.

With the possible exception of patients with pernicious anemia who were generally maintained on high-purine diets, in whom acute articular episodes might be precipitated by injections of liver extract, there has been no relationship between the biochemical phenomena associated with gout and those that attend the administration of the drugs observed to precipitate acute attacks. In all instances, the mechanism of this reaction was thought to be general rather than specific. In the cases that followed administration of a diuretic agent, the mechanism was thought to be the abrupt shift in electrolytes produced by the diuresis rather than any specific effect of the diuretic agent itself on urate metabolism. In patients with acute gout induced by chlorothiazide diuresis, this concept is clouded by the frequent observation of hyperuricemia after chlorothiazide therapy. However, the appearance of clinical symptoms does not appear to be related to the degree of serum uric acid level elevation. Clarification will have to await a better understanding of the pathophysiology of gout, the relationship between the metabolism and excretion of uric acid and the acute articular episode, and, finally, whether the hyperuricemia produced by chlorothiazide involves a similar mechanism or merely represents a nonspecific effect of this drug on the kidneys.

Prevention of Articular Episodes.—For the present, it appears propitious to avoid the use of chlorothiazide and other benzothiadiazine compounds in patients with a history of gout and to suspect the possibility of gout in patients treated with these drugs who complain of aching and painful joints, especially of the feet. Since these complaints are commonly encountered among patients in the age groups likely to require chlorothiazide therapy, such a suspicion will be aroused rather frequently. Although it would be interesting to observe the fluctuations in serial serum uric acid level determinations in these persons, the lack of correlation between this finding and clinical gout would render it of little value in establishing the diagnosis. A prompt subsidence of the symptoms after the cessation of chlorothiazide therapy and, when severe enough, the concurrent administration of a standard course of colchicine, would tend to confirm it. In such cases, it would probably be wise to abandon therapy with chlorothiazide in favor of one of the other diuretic agents which induce hyperuricemia and acute gout much more rarely, if at all.

The possible use of probenecid to prevent the retention of uric acid and thereby diminish the likelihood of such acute articular episodes has been suggested. Its value in the management of gout is well established. Beyer[12] demonstrated in dogs that the simultaneous intravenous administration of probenecid and chlorothiazide diminished the renal clearance of the latter but did not appear to alter greatly its diuretic action. This is countered by personal experiences (case 2) in which probenecid administration appears to have been followed by a response to a subsequent diuretic agent less marked than was anticipated. It remains to be determined whether such inhibition of diuresis is sufficient to make the combination of probenecid and chlorothiazide significantly less satisfactory than the use of another diuretic agent alone. Even if this were so, additional studies would be needed to determine whether the simultaneous administration of probenecid would significantly compromise the usefulness of chlorothiazide in antihypertensive regimens.

Summary and Conclusions

Acute articular episodes of gout were precipitated by chlorothiazide-induced diuresis in two patients. Hyperuricemia is a relatively frequent concomitant of chlorothiazide administration and appears to result from diminished urate excretion. Gout should be suspected in patients who, under treatment with chlorothiazide or with one of the other benzothiadiazine compounds, complain of arthralgia. The symptoms and the hyperuricemia subside promptly when chlorothiazide therapy is interrupted. Colchicine may be used when the arthritic symptoms are severe.

Although the mechanisms by which chlorothiazide produces hyperuricemia, and the relationship between this hyperuricemia and the clinical manifestations of gout, are not clearly understood, these phenomena are a drawback to the use of this drug, especially in patients with a history of gout.

ANTIBIOTICS IN DENTAL CONDITIONS.—Antibiotic therapy has been abused by both the dental and medical professions. Antibiotics are not innocuous agents and their use is often attended by complications far in excess of the disease entity they were supposed to cure. When these agents are used, they must be used long enough and in dosage strong enough to give a therapeutic result. Antibiotics are not a substitute for careful diagnosis or surgery or meticulous operative technic. If good antibiotic medicine is to be practiced, constant study of the current dental and medical literature on the part of the dentist or physician is essential, and changes of trends in therapy must be noted. Full use should be made of relevant data. The regular use of antibiotics is fully justified when dental surgery is to be performed in patients who are afflicted with any of the following conditions: rheumatic heart disease, congenital heart disease, subacute bacterial endocarditis, rheumatoid arthritis, diabetes or renal disease, or for patients on steroid therapy or receiving radiation for malignant tumors of the head and neck. It must be remembered that these patients are all debilitated to some extent, at least physiologically if not physically, and should not be subjected to any secondary dental infection if at all possible. Usually broad spectrum antibiotics have been found to be most adequate.—E. J. Degnan, D.D.S., Use and Abuse of Antibiotics in Dentistry, *Journal of Oral Surgery, Anesthesia and Hospital Dental Service,* November, 1959.

LABORATORY DATA ON THE DETROIT POLIOMYELITIS EPIDEMIC—1958

Gordon C. Brown, Sc.D., Ann Arbor, Mich., Willard R. Lenz, M.D., Detroit
and
George H. Agate, M.D., Lansing, Mich.

During an epidemic of poliomyelitis in Michigan in 1958, virological and serologic studies were carried out with specimens from 1,060 patients. Fecal specimens from 869 patients yielded no virus in 401 cases, poliovirus in 292, ECHO (enteric cytopathogenic human orphan) virus in 100, Coxsackie virus in 73, and unidentified virus in 3 cases. Serums from 191 patients from whom no fecal specimens were obtainable showed no antibody changes in 123 cases but did show changes diagnostic for poliovirus in 48, ECHO viruses in 14, and Coxsackie virus in 6. In a large number of paralytic as well as nonparalytic patients poliovirus was not the cause. Frequency studies showed that there were no obvious clinical differences among infections with Coxsackie, ECHO, and poliomyelitis viruses. Coxsackie and ECHO viruses were responsible for more cases of "nonparalytic poliomyelitis" and "aseptic meningitis" than was poliovirus itself. This, added to the fact that two immunological types of the poliovirus were involved in the epidemic, suggests the difficulty to be anticipated in future programs of immunization.

During 1958 the state of Michigan experienced its largest epidemic of poliomyelitis in many years, with more than 1,200 cases reported to the state department of health. Most of the victims resided in Detroit and its immediate environs, and a preliminary report describing the occurrence and distribution of cases in that metropolitan area has been published.[1]

For several years the virus laboratory of the University of Michigan has performed diagnostic tests on specimens obtained from patients diagnosed as having poliomyelitis and has reported the findings to the hospitals that submitted the specimens, to the state department of health, and to the United States Public Health Service. Hence, prompt arrangements were made for the collection of stool and blood specimens as well as clinical histories on the cases occurring in 1958 as soon as the patients were hospitalized. Virological laboratory tests were carried out on 1,060 persons, probably the greatest percentage of victims of a large epidemic of poliomyelitis ever to be subjected to laboratory investigation.

Method of Testing

Through the cooperation of the medical staffs of the various hospitals involved, stool specimens and serums obtained during the acute and convalescent phases of poliomyelitis were collected and sent to our laboratory. Appropriate information such as name, age, sex, address, date of onset, vaccination history, and clinical findings accompanied the specimen obtained from each patient. Stool specimens were prepared by the addition of three volumes of tissue-culture fluid containing antibiotics, the mixture then being shaken in Lusteroid tubes with glass beads for 20 minutes. The resulting emulsions were centrifuged first at 2,000 rpm for 30 minutes and then at 10,000 rpm for 45 minutes, after which the supernatants were placed directly into tubes containing monolayer cultures of monkey-kidney cells. Specimens from paralytic patients were retested if the findings had been negative for virus on the first attempt. Virus isolations, as determined by cytopathogenicity, were typed with known hyperimmune reference serums, to determine their immunological identity. If an agent was found not to be poliovirus, it was tested against all 24 types of enteric cytopathogenic human orphan (ECHO) virus serums and against those of Coxsackie virus types A9 and B1 through B5.

Paired serums obtained during the acute and convalescent stages of the illness were tested for antibody content by neutralization tests in plastic panel cultures of monkey-kidney cells against 100 tissue-culture doses (TCD_{50}) of appropriate reference viruses.

Results

Stool specimens were available from 869 patients, and on 191 additional persons from whom no stool specimens had been collected a diagnosis was made by testing the serums obtained during the acute and convalescent phases of poliomyelitis. The results of attempted virus isolation from stools are presented in table 1, where it will be seen that an agent was obtained from 245 of 567 patients whose diagnosis on admission had been nonparalytic, or suspect poliomyelitis or aseptic meningitis. Virus was isolated from 223 of 302 patients who had been

classified as having paralytic or bulbar cases of poliomyelitis. Table 2 presents the results of serologic tests on patients from whom no stool specimens were available, and it will be seen that the etiology of illness could be identified both in an additional 35 of 143 nonparalytic patients as well as in 33 of 48 paralytic patients. Because of these extensive tests several significant observations can be made.

Types of Poliomyelitis Virus.—The epidemic involved two immunological types of poliomyelitis virus. Of the poliomyelitis viruses recovered from nonparalytic patients, 57 were found to be type 1 and 17 type 3. Of the polioviruses obtained from the paralytic patients, 177 were shown to be type 1 and 41 type 3. Serologic tests on specimens obtained from patients from whom no fecal specimen was available likewise indicated the presence of these two types of virus as causative agents. Two paralytic patients appeared to have dual poliovirus infections, since both types of virus were isolated from the same stool specimen. Two children, both in the same family, were hospitalized on Aug. 8, 1958, with a diagnosis of nonparalytic poliomyelitis shown to be due to a type 1 virus infection. After recovery and release they were both readmitted to the hospital on Oct. 1, 1958, with the same diagnosis, and this time type 3 virus was recovered. Serologic tests on blood specimens obtained during both illnesses proved that these children had each experienced separate infections with two different immunological types of poliomyelitis virus within a period of two months.

Viruses Other than Poliomyelitis.—ECHO viruses were isolated from 97 of the persons hospitalized with nonparalytic infections; in 94 of these the agents were identified as type 9 ECHO virus and in 3 as type 6. Nonparalytic infections in 71 persons were caused by Coxsackie viruses, of which 55 were due to type B5. Coxsackie type A9 was isolated 9 times, type B2 twice, and type B3 thrice; three isolates are still unidentified. Thus these viruses were the cause of nonparalytic disease more frequently than was poliovirus (see table 1).

It was of considerable interest that the ECHO 9 virus was associated with paralytic disease in three persons and the Coxsackie B5 in two. Serologic tests indicated that three additional paralytic illnesses were caused by these agents.

Relation of Vaccination to Incidence.—Table 1 clearly shows that most of the virus-confirmed cases of poliomyelitis had occurred in persons who had received no poliomyelitis vaccine. Forty-four of the 74 nonparalytic patients and 164 of the 218 classified as paralytic were unvaccinated. The number of virus-confirmed paralytic cases decreased among persons who had received one or more doses of vaccine, as is borne out by the fact that only 11 patients were found to have been vaccinated three or more times. Table 3 combines the results in tables 1 and 2 and expresses the findings in terms of the percentage distribution of all patients according to their vaccination history.

The percentage distribution of patients with virus-confirmed poliomyelitis who had a history of three doses of poliovirus vaccine was definitely lower than that among persons with fewer inoculations. While there was little difference between the unvaccinated and those reported to have had only one dose, the percentage of negative findings increased progressively in persons who had been given two and three doses of poliovirus vaccine. The percentage of nonparalytic cases confirmed as poliomyelitis decreased steadily from 21% among the unvaccinated to 6% in patients who had received three injections. Among the nonparalytic cases it can be seen that, regardless of the number of persons in each vaccine group, from 58 to 63% were negative for virus, a remarkably constant finding. The occurrence of ECHO and Coxsackie virus infections was not influenced by poliomyelitis vaccination.

Correlation of Serology and Virology.—Antibody determinations were possible on 185 of the 292 patients from whom poliovirus had been isolated. In all but two of these patients the antibody pattern was consistent with the immunological type of virus recovered. Most of the serums obtained in the acute phase of the disease contained type-specific antibodies to a titer of 1/64 to 1/256, confirming previous observations that antibody develops early during the incubation period in this disease. Only 52% of patients showed a further rise in titer during convalescence, but the presence of specific antibodies to one type in high titer in the absence of antibodies to the other types is known to have significance in the diagnosis of poliomyelitis. In fact, the present results closely approximate those reported in the final report of the field trial in 1954.[2]

TABLE 3.—*Percentage Distribution of 1,060 Patients with Poliomyelitis by Vaccination History*

		Nonparalytic Cases, Virus, %						Paralytic Cases, Virus, %			
No. of Vaccinations	Total	Negative	Polio	ECHO	Coxsackie	Undetermined	Total	Negative	Polio	ECHO	Coxsackie
None	245	58	21	13	7		241	21	77	2	
1	37	59	16	11	13		38	13	87		
2	113	63	12	13	10	2	30	40	60		
3	315	62	6	18	13	0.3	41	63	29	2	4
	710						350				

Paired serums were available for testing on 201 of the 322 nonparalytic patients from whom no virus could be isolated. With use of the same criteria of antibody patterns as those applied in the patients from whom virus was isolated, only 23, or 11%, of the nonparalytic patients showed antibody changes diagnostic of poliomyelitis and one for ECHO type 9 infection. Paired serums were obtained from 58 of the 79 virus-negative paralytic patients, and 14, or 24%, of these showed changes diagnostic of poliomyelitis. Of these 14 paralytic patients, 11 whose serologic findings were positive were unvaccinated, and the remaining 3 had received two doses of poliovirus vaccine. Thus the serologic results obtained in specimens from patients from whom no virus was isolated indicate that the isolation technique was about 90% effective for the nonparalytic patients and 75% effective with those who were paralytic, suggesting strongly that poliovirus was not the cause of illness in a large number of both paralytic and nonparalytic patients.

ECHO virus type 9 serologic determinations were performed on 71 of the 97 patients from whom that virus had been isolated. All but one had antibodies in the specimen obtained in the acute stage of the illness, mostly of a high titer, and 49 patients, or 70%, showed a further rise in titer during convalescence. The titers of poliomyelitis antibodies remained unchanged in all but three of these patients. The concurrent rise in poliomyelitis antibody in these latter three patients suggests the possibility of otherwise undetected dual infection.

Coxsackie type B5 serologic investigation was performed for 32 of the 55 patients whose stools contained that virus. All but 3 had antibodies in the specimen obtained during the acute phase, and 23, or 72%, showed further development of antibodies during convalescence. The presence of type-specific antibodies and the demonstration of increased antibody production in about 70% of the patients from whom ECHO and Coxsackie viruses were isolated indicated that it was these agents that were responsible for the illnesses and not merely latent or carrier viruses. This is particularly significant with respect to paralytic disease. Paired serums were available from two paralytic patients from whom ECHO 9 virus had been recovered and from one patient, who had a fatal case, who excreted Coxsackie B5. In each instance there was a rise in type-specific antibodies.

Multiple Infections in Families.—There were 34 families in which two or more members were hospitalized during the epidemic. Twenty-eight families had two members hospitalized with a tentative diagnosis of poliomyelitis. The infection was shown to be due to ECHO 9 virus in eight families and Coxsackie B5 in three; all others were clearly due to poliovirus type 1 or 3. Three members from each of four families were hospitalized. Two of these families were shown to be infected with poliovirus and one with ECHO 9. Two persons in the fourth family were infected with type 1 poliovirus and one with Coxsackie B5. Of the two families with four cases, all patients were infected with type 1 poliovirus.

Age Distribution.—Table 4 shows the distribution by age of the patients examined in the laboratory. It is obvious that the virus-confirmed cases of poliomyelitis occurred predominantly in younger persons, whereas Coxsackie and ECHO virus infections were much more evenly distributed by age, especially among those less than 14 years of age, as were the persons from whom no virus could be isolated.

Correlation of Clinical and Laboratory Findings.—Since it is difficult to differentiate various enterovirus infections on a clinical basis alone, an attempt was made to collect appropriate clinical findings on as many patients as possible from whom either Coxsackie or ECHO viruses had been isolated. The percentage of occurrence of signs and symptoms associated with these infections is presented in table 5. No obvious clinical differences between the two infections were apparent; in fact, the findings showed a remarkable similarity. Furthermore, there was no predominant finding which separated either infection from nonparalytic poliomyelitis. It is of interest that a history of rash, commonly thought to be associated with ECHO 9 infection, was obtained in only 7% of such cases. The spinal fluid cell counts on most of these cases were available and are compared in table 6 with counts from patients with both paralytic and nonparalytic poliomyelitis as well as with those from patients from whom no agent could be recovered. While most of the virus-confirmed poliomyelitis patients had spinal fluid cell counts of less than 200 per cubic millimeter, infections with Coxsackie and ECHO virus were frequently associated with much higher counts, especially the former. Protein and sugar levels in the spinal fluid of patients with ECHO and Coxsackie infections were above normal, as in patients with poliomyelitis. Fluid from patients with ECHO infections, however, was characterized by the low number of polymorphonuclear cells and a very high lymphocyte count in the spinal fluid, frequently 100%. In contrast, fluid from patients with Coxsackie infections was associated with the reverse picture, i. e., high polymorphonuclear and low lymphocyte percentages.

An additional correlation of clinical and laboratory information was made possible by the fact that 550 of the patients in the Detroit area were examined for muscle weakness 60 days after onset of disease. The results are presented in table 7 in terms of the degree of paralysis two months after infection, and they are arranged according to the clinical diagnosis at the time of admission to hospital and according to the results of laboratory tests carried out on specimens from these patients. It is obvious that most of the 308 patients considered to be nonparalytic on admission were also classified in that category two months later. Virus was isolated from only one-half of those among whom ECHO and Coxsackie viruses were equally responsible with poliovirus for the infections. Among the 242 patients originally diagnosed as

§ P_3 = severe paralysis or death

paralytic, 187, or 77%, were confirmed by laboratory tests to have poliomyelitis. The vast majority of these (84%) were found to have residual paralysis 60 days after onset of the illness, and it is of interest that 83% of these paralytic patients were unvaccinated and only four, or 2.5%, had received three doses of vaccine. Twenty-one of the 29 patients who had changed to nonparalytic status by the time of the muscle examination 60 days after onset were also unvaccinated, and only one had received three doses; this indicates that vaccination was not associated with their improved muscle status. Of the original 53 paralytic patients not confirmed as having cases of virus infection only 33, or 62%, had residual paralysis after two months, only one-half were unvaccinated, and 22% had received three doses of poliomyelitis vaccine; this demonstrates that a history of complete vaccination was much more frequent among patients with paralytic cases which were not confirmed than among those whose illness proved to be poliomyelitis.

Comment

The availability of stool and blood specimens from such a high percentage of patients in a large epidemic of poliomyelitis provided an unusual opportunity to study the laboratory aspects of the infections and to elucidate information which would not have been apparent from clinical observation alone. One such example was the fact that two immunological types of poliovirus (1 and 3) were incriminated in the epidemic. This finding illustrates the necessity of immunization against more than one type of poliovirus. Examples of dual infection, either simultaneously or within short periods of time, emphasize the importance of this concept.

A correlation of virus-confirmed cases of poliomyelitis with the patients' history of vaccination clearly shows the suppressive effect of vaccine on clinically recognizable disease. This was apparent not only for the patients with paralytic cases but also for those classified as nonparalytic.

Serologic studies on large numbers of serum specimens obtained during the acute and convalescent phases of the illness served the dual purpose of confirming the etiology of the disease in cases in which a given virus had been isolated and also furnishing additional information on the serologic patterns which accompany these infections. This can be particularly valuable in instances in which no stool specimen is available for virus isolation.

The multiplicity of infection in 34 families was shown to be a characteristic of ECHO and Coxsackie viruses as well as of poliomyelitis. In fact, both poliomyelitis and Coxsackie viruses were isolated from members of one family at the same time.

The large number of ECHO and Coxsackie virus infections in persons with nonparalytic disease exemplified the increasing importance of these viruses in clinical medicine. In fact, these agents were responsible for more cases of "nonparalytic poliomyelitis" and "aseptic meningitis" than was poliomyelitis virus itself. Although a variety of enteroviruses was encountered, two in particular, the Coxsackie B5 and the ECHO 9, were found to be the most prevalent. In fact, 1958 was the second successive year of high incidence of the latter agent. Since these viruses can apparently cause a paralytic type of disease in an occasional person, consideration should be given to the development of preventive vaccines for certain of these agents. This is especially important for pregnant women, in view of the increasing recognition of neonatal deaths caused by Coxsackie B viruses, as recently summarized by Kibrick and Benirschke.[3] Two examples of this have recently been observed in our laboratory.[4] Coxsackie B2 virus was isolated from the heart, brain, lung, and intestinal contents of a child who died 15 days after birth. His mother had experienced only a low-grade fever at the time of delivery, and a sibling had a "sore throat" at that time. Coxsackie B3 virus was isolated from the heart of another infant who died five days after birth. The mother of this child had experienced only low-grade fever and malaise two days prior to delivery.

An attempt to correlate clinical findings with virus-confirmed ECHO and Coxsackie infections revealed that fever, headache, and meningeal irritation were the most frequent signs and that these infections were usually associated with higher spinal fluid cell counts than were cases of poliomyelitis.

A muscle examination performed 60 days after the onset of illness on 550 patients showed that 94% of those diagnosed as nonparalytic remained in that category regardless of the laboratory findings. Of the patients with virus-confirmed paralytic disease, 84% had residual paralysis two months later, 77% were unvaccinated, and only 2.5% had received three injections of vaccine. Fewer of the paralytic patients (62%) in whom poliomyelitis was not confirmed had residual paralysis. Although most of them were unvaccinated, 60% of those who became nonparalytic had received three injections of poliomyelitis vaccine.

Summary

Virological, or serologic determinations, or both, were performed on 1,060 patients who were hospitalized during the 1958 epidemic of poliomyelitis in Michigan. The results show that two immunological types of poliovirus were involved but also that certain types of ECHO and Coxsackie viruses were prevalent; in fact, they were together responsible

for more laboratory-proved cases of nonparalytic poliomyelitis and aseptic meningitis than was poliomyelitis virus itself. The vast majority of virus-confirmed cases of poliomyelitis occurred in unvaccinated persons, and 84% of these with paralysis still showed residual muscle impairment 60 days later.

HEAD-TILT METHOD OF ORAL RESUSCITATION

James O. Elam, M.D., David G. Greene, M.D., Max A. Schneider, M.D., Buffalo
Henning M. Ruben, M.D., Copenhagen, Denmark, Archer S. Gordon, M.D., Ph.D., Los Angeles
Robert F. Hustead, M.D., Donald W. Benson, M.D., John A. Clements, M.D., Baltimore
and
Arne Ruben, M.D., Karlskrona, Sweden

Mouth-to-mouth and mouth-to-nose methods of artificial respiration are simplified and made more effective if the patient's neck is extended by the procedure here described. With the patient in the supine or semilateral position, the rescuer uses one hand to tilt the patient's head as far back as possible. He uses his other hand to pull the patient's chin upward. Circumstances determine whether the rescuer will apply his mouth to the mouth or the nose of the patient. The use of adjuncts like tubes and masks by untrained laymen in order to avoid direct contact is not recommended.

Since the publication of the symposium on mouth-to-mouth resuscitation in The Journal, May 17, 1958, page 317, improved techniques have been established for performing expired air resuscitation, now called oral resuscitation. Results from a coordinated program of investigation in seven research centers are in agreement about the advantages and workability of the simplified technique as regards effectiveness, practicality, and ease of learning and remembering.

In December, 1958, studies in apneic unconscious volunteers and patients, both curarized and noncurarized, were initiated in seven research centers by us and by cooperating rescue personnel in six metropolitan areas: Buffalo; New York City; Los Angeles; Copenhagen, Denmark; Karlskrona, Sweden; and Zurich, Switzerland. After one year of these coordinated studies in over 1,000 anesthetized human beings, results of use of the head-tilt oral method, with inflation through the victim's nose, have been uniformly satisfactory except in the group of newborn infants, which involves special problems. These extensive successful trials of the head-tilt oral resuscitation method prompt the revision of previously recommended methods, which it supersedes. This simple technique has already been taught and demonstrated to over 10,000 lay trainees.

Difficulties with Previous Techniques

Control of the air passages by (*a*) pulling on the jaw with the thumb in the victim's mouth or (*b*) pushing upward at the angles of the jaw presents problems in performance and teaching. Difficulties in performance have been as follows. 1. Leakage around the rescuer's thumb in the victim's mouth is often excessive. 2. Inflation of the relaxed victim's stomach during both mouth-to-mouth methods has been a frequent complication, aggravating passive regurgitation of stomach contents. 3. Trismus has complicated or prevented inflation through the victim's mouth. (For example, the 1959 President's

Ruben); the Children's Hospital (Dr. Gordon); Johns Hopkins University School of Medicine (Drs. Hustead and Benson); Army Chemical Center, Maryland (Dr. Clements); and Centrallazarettet (Dr. A. Ruben).

medal of the National Safety Council was awarded for a successful mouth-to-nose resuscitation of an asphyxiated victim in an industrial accident. The victim was found deeply cyanotic and "rigidly unconscious." His jaws were too tightly clenched to be opened. Head-tilt and mouth-to-nose inflations restored full consciousness in three minutes.) 4. Both methods are fatiguing for the rescuer's hands. 5. Insertion of the thumb in the victim's mouth through sharp teeth is hazardous, especially in near-conscious victims.

Difficulties in teaching may be summarized as follows. 1. Pulling on the jaw with the thumb or pushing upward at the angles of the jaw involves numerous fine details in technique which cannot be learned by some laymen. The average layman, unaware of the anatomy of airway obstruction, has difficulty understanding and remembering the rationale for these maneuvers to displace the mandible. 2. The modifications for infants and children are different from the procedures used on adults. 3. Insertion of the thumb in the mouth during practice is frequently distasteful. 4. Both methods are impractical and often impossible to demonstrate and practice effectively on conscious volunteers. The practice victim often cannot relax his chest or keep his glottis open. He cannot relax his jaw muscles to allow forward displacement, which may be quite painful. 5. The instructor cannot evaluate whether trainees have learned these procedures.

Head-Tilt Oral Resuscitation

Advantages.—All of the objections to the previous techniques have been overcome with the head-tilt method of resuscitation, particularly when first preference is given to the nasal route of inflation of the victim's lungs. Gastric inflation by this route is negligible or absent, apparently as a result of the resistance to airflow through the nose. Whether the nose or mouth is used, leakage is not a problem. During mouth-to-nose breathing, the victim's mouth is held closed. During mouth-to-mouth breathing, the rescuer presses his cheek against the victim's nostrils, if necessary, to prevent leakage. The same method is equally suited to the victim with the tight jaw, as illustrated by the successful mouth-to-nose case cited above. Despite trismus, the head can be tilted and this action opens the nasopharyngeal and glottic air passages.

The simplicity and ease of evaluating performance of the method are major advantages. Experience has shown that it can be taught and practiced in a few minutes, with minimal discussion of the anatomy of the air passages. It is easy for casual rescuers to remember the simple steps of tilting the head back as far as possible and inflating the lungs through the nose or mouth.

Performance.—Instructions for head-tilt oral resuscitation are as follows. 1. Lift the neck (fig. 1*A*). 2. Tilt the head as far back as possible by holding the crown of the head with one hand. (Sufficient tilting usually opens the victim's mouth.) 3. Pull the chin upward with the other hand (fig. 1*B*). (X-ray studies show this action produces a wider open air passage than that of normal conscious subjects.) 4. Inflate the lungs through the nose or mouth or, in an infant, through the nose and mouth (fig. 1*C*). 5. Remove your mouth to let the victim exhale passively (fig. 1*D*). (If necessary, let him exhale through his mouth by momentarily separating his lips.)

The position of the rescuer's hands and the wide area of the oral seal must be emphasized for successful performance of this method. Both the rescuer's hands continuously maintain maximum extension of the head (fig. 2, *left*). Nasal inflation is preferred, to avoid gastric dilatation. Inflation through the victim's mouth in the event of nasal blockage merely requires separation of his lips with the rescuer's thumb, which is already in place on the victim's chin (fig. 2, *center*). In babies and children care must be taken to pull the chin upward, without exerting pressure on the soft tissues, which could encroach on the air passages (fig. 2, *right*).

An important modification is the optional use of the semilateral position for the victim. The victim's shoulder may rest continuously on the rescuer's knee during resuscitation (fig. 3). From this position, the victim's head is easily tilted to provide gravity drainage of fluid from the pharynx (fig. 3, *inset*). Small victims, particularly after submersion in water or obstruction by a foreign body in the upper airway, should be inverted and, if necessary, sharp blows applied between the shoulder blades to help dislodge the offending material (fig. 4).

The head-tilt oral method fulfills the need for a simple and effective universal procedure for resuscitating children and adults. Maximum extension of the victim's head opens and keeps open the air passages by the simplest known maneuver, without involving insertion of the finger or equipment into the mouth.

Oral Resuscitation by Laymen Without Adjuncts

Confusion has arisen from the failure to make a distinction between casual and trained rescuers. It should be emphasized that methods of resuscitation available to the general public must be simple, safe, and easily learned and must require no adjunct.

A compilation of data in "Accident Facts," a booklet published by the National Safety Council, indicates that approximately 11,000 deaths per year occur as a result of asphyxia or suffocation.

Records for 1957-1958 indicate that two-thirds of initial resuscitation attempts are made by housewives or passers-by. Thus, the major criticism of adjunctive equipment for resuscitation is that these nonprofessional rescuers who account for the majority of rescues cannot be expected to have the adjuncts with them at all times and should not be encouraged to spend the time required to find them in an emergency. Specialized techniques involving equipment should be considered only for persons trained in (*a*) the management of the air passages and (*b*) artificial ventilation of the unconscious patient.

Another difficulty besetting the casual rescuer is that he cannot diagnose with certainty the level of reflex response of the unconscious patient. He will attempt artificial respiration in any apparently unconscious person. Methods which simply require contact with the face and inflation through the nose or mouth can do little harm under any circumstances. In contrast, the hazards of instrumentation of the throat of a semiconscious victim with an active gag reflex are laryngospasm or vomiting and aspiration. If rescue efforts involve manipulations in the pharynx, a victim of asphyxia is prone either to vomit or to regurgitate passively, with the resulting danger of acid stomach contents entering his lungs. Unlike the anesthetized, curarized volunteer, an asphyxia victim is not likely to have an empty stomach, has not received belladonna to diminish secretions and to suppress vagal reflexes, has not been depressed by anesthetic drugs, and has not been paralyzed by curare sufficiently to prevent retching and vomiting. Efforts at opening the mouth of a victim of asphyxia in the early stages are likely to be traumatic or to fail completely, since such victims have an interval of increased skeletal muscle tone, including trismus. Despite these difficulties, the nasopharynx or air passages around the teeth may well be available under these circumstances. Failure to use them promptly may result in failure of resuscitation.

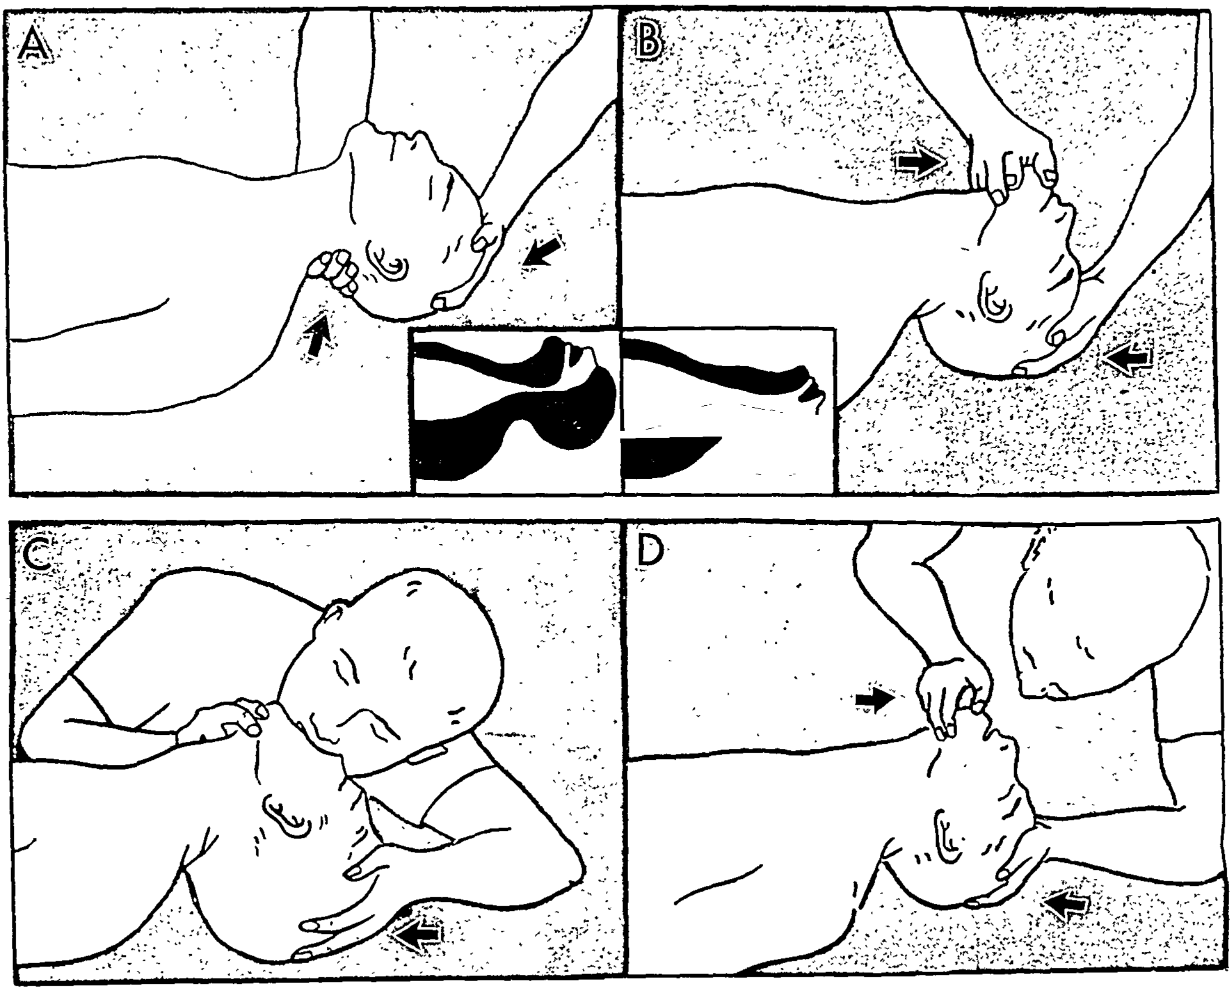

Fig. 1.—Head-tilt oral method. *A*, neck is lifted; *B*, head is fully tilted back; *C*, lungs are inflated via nose or mouth; and *D*, victim exhales by himself, if necessary, through his mouth.

Furthermore, considerable skill and experience are required in the proper use of the artificial oral airway, except in the deeply flaccid person. Experience is necessary, however, even then, to choose the right size to prevent trauma and to avoid pushing the tongue back to further block the air passages.

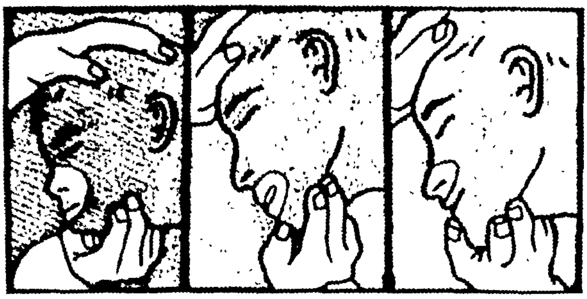

Fig. 2.—Wide area of seal around nose, mouth, or both: important detail in head-tilt oral method.

Since it is possible to prevent airway obstruction simply by maintaining the victim's head in the proper tilted position and employing either the oral or the nasal routes of inflation, commercial claims that resuscitation appliances work better than direct expired-air resuscitation lack substance in fact. In the seven reporting research centers, comparisons of efficiency and speed of resuscitation with and without adjuncts have repeatedly demonstrated the superiority of direct mouth-to-nose and mouth-to-mouth breathing by both professional and lay personnel. Furthermore, the use of any adjunct, even when it is readily available, causes delay in starting inflation of the lungs, even though this delay may be minimal. The several hundred successful resuscitations performed by laymen without adjuncts which have been reported in the last two years suggest that laymen will perform oral resuscitation without adjuncts.

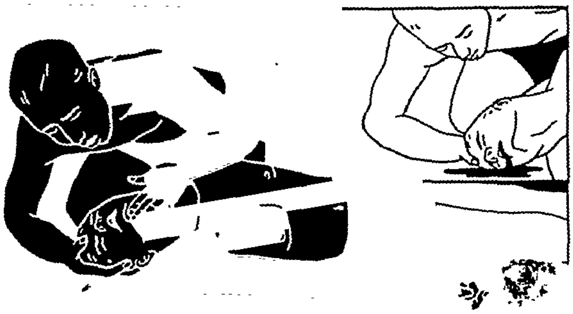

Fig. 3.—Semilateral position for gravity drainage of fluid from victim's oropharynx. Victim's shoulder should be pulled up on rescuer's knee. Gentle pressure should be used over epigastrium to facilitate emptying fluid from stomach.

Before the rescuer can safely use an oral airway in an emergency, he should understand how to test and to judge reflexes in patients after head injury, heart attack, convulsions, drug overdose, and electric shock. The layman who lacks experience in these emergencies should use the head-tilt method of oral resuscitation, with or without a handkerchief.

This head-tilt oral method of resuscitation fulfills the need for a universal method which opens the air passages and keeps them open by the simplest possible maneuver, does not involve insertion of the finger or equipment into the mouth, and is easy to teach and remember. It was officially adopted by the Holger-Nielsen committee of the Danish Red Cross, effective Oct. 7, 1959.

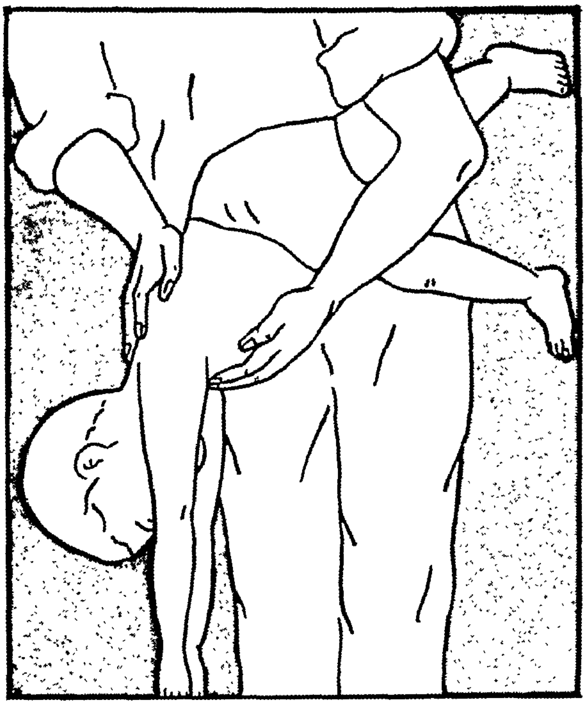

Fig. 4.—Method for dislodging obstructing material from child's throat. Victim should be inverted and sharp blow applied between shoulder blades.

Recently, the promotion and sale to the public of oral airways for resuscitation has been undertaken by commercial firms without official medical approval or the approval of organizations traditionally responsible for endorsement of methods of artificial respiration. We believe that (1) adjuncts (tubes and masks) should not be used by untrained laymen and (2) the head-tilt oral method, with use of the nasal or oral route of inflation, is the preferred technique to be tried first in all cases. The head-tilt method of oral resuscitation works better than any other field method of emergency artificial respiration, and, because of its simplicity, it is more easily learned than any other method.

CLINICAL NOTES

SPONTANEOUS RUPTURE OF THE SPLEEN AFTER ACUTE PANCREATITIS

REPORT OF A CASE

Robert H. LaBree, M.D., Josiah Fuller, M.D.
and
Paul G. Boman, M.D., Duluth, Minn.

In 1955, Byrd and Couch[1] reported a case of spontaneous rupture of the spleen with hemorrhagic left pleural effusion after pancreatitis. At laparotomy a huge hematoma had been found in the left upper quadrant of the abdomen. According to these authors, no previous similar case had been reported. In 1917, Turner[2] documented a case wherein splenic rupture, due to splenic infarct, was associated with hemorrhagic pleural effusion. In each instance, hemorrhagic left pleural effusion without previous injury to the thoracic cage was present.

An aftermath of acute, or recurrent, pancreatitis is the formation of many perisplenic adhesions which pull on the relatively mobile spleen and produce a shearing effect; this results in tearing of the soft, friable splenic tissue. In the patient we are reporting occupation may have played an important role; his job required driving a delivery truck over rough roads and repeatedly jumping in and out of the truck cab.

A 45-year-old man was admitted to St. Luke's Hospital on March 25, 1955, with complaints of constant pain in the left upper quadrant of the abdomen, weakness, belching, a 30-lb. (13.6-kg.) weight loss, anorexia, and dyspnea with fatigue on even slight exertion since November, 1954. The history was significant. The patient lived with his brother and cooked his own meals. The patient's brother and friends gave a history of heavy drinking by the patient. In November, 1954, the man had been under the care of another physician for persistent, sharp, and severe epigastric distress with radiation to the left upper quadrant of the abdomen and to the left flank. At that time, a serum amylase determination was reported to have been 456 units. A physical examination had revealed tenderness, guarding, and tympany over the entire upper part of the abdomen. The bowel sounds were said to be decreased. His physician at that time had believed the diagnosis to be acute pancreatitis. Compatible conservative therapy was started, and the patient improved, being discharged from his local hospital on Dec. 21, 1954. The attending physician later reported that at no time had an abdominal mass been palpable. In February, 1955, a cholecystogram was reported to have shown negative results. In March, the patient returned to his attending physician, complaining of pain in the left upper quadrant of the abdomen. One week later, the patient came under our observation.

Physical examination on March 25, 1955, revealed an extremely ill, pale, patient. Weight loss, weakness, and dyspnea were obvious. The examination of the abdomen revealed tenderness in the left upper quadrant. No mass was felt. The laboratory data showed the hemoglobin level to be 5 Gm. per 100 cc. (34%), the white blood cell count 14,250 per cubic millimeter, and the sedimentation rate 37 mm. per hour (Westergren). Further studies in the hospital indicated a lesion involving the left subphrenic space. Chest fluoroscopy and roentgenograms revealed elevation of the left part of the diaphragm, with immobility, plus definite evidence of a fluid collection in the left costophrenic sulcus. Aspiration of the fluid in the left side of the chest was not done.

Several days were spent correcting symptoms of dehydration and improving the general health of the patient. A preoperative diagnosis of rupture of the spleen associated with a left subphrenic hematoma, due to previous acute pancreatitis, was considered. On April 1, 1955, an operation was performed by way of a left subcostal incision. Exploration revealed a huge subphrenic hematoma on the left. After evacuation of the old blood, further search revealed a small pancreatic pseudocyst and indisputable evidence of recent fat necrosis. For several reasons, splenectomy was not performed and the abdomen was closed after two large Penrose drains had been placed in the left subphrenic space.

Recovery was slow but steady. In August, 1955, the patient returned to us with evidence of a large pancreatic cyst. On Aug. 31, 1955, this large cyst was marsupialized. The amylase level in the fluid obtained from the cyst at the time of operation was 1,900 units per 100 cc. Subsequent closure of the cyst was greatly facilitated by the use of an indwell-

---

From the Department of General and Thoracic Surgery (Dr. LaBree and Dr. Fuller) and the Department of Internal Medicine (Dr. Boman), the Duluth Clinic.

ing catheter connected to a Stedman pump to drain the cyst and the administration orally of methantheline (Banthine) bromide to discourage pancreatic activity.

Since his recovery from the latter operation, the patient has had two episodes of mild but definite pancreatitis. These episodes necessitated hospital care; serum amylase values were found to be elevated in each instance. Presently, the patient is doing well and is allegedly avoiding the consumption of alcohol. Repeated roentgenographic studies of the gallbladder and gastrointestinal tract have revealed normal findings.

CLINICAL SCIENCE

BLOOD NUCLEOTIDES

Charles Bishop, Ph.D., Buffalo

The statement is made frequently that uric acid is the end-product of purine metabolism in human beings. The serum level and urinary excretion of this compound have been extensively studied, particularly in patients with diseases such as gout, who show marked increases in urate levels. With the advent of chromatography and radioactive isotopes it has become possible to study some of the purine compounds that give rise to uric acid in the body. Because the purines are essential to life it is not surprising that these newer studies are touching many areas of medicine.

The body purines do not usually occur as free compounds but are ordinarily bound to molecules of sugar and phosphate. This combination of a purine such as adenine, a pentose sugar such as ribose, and phosphate is called a nucleotide. This particular adenine nucleotide is called adenylic acid, or adenosine monophosphate (AMP). More phosphates can be added to form the compounds adenosine diphosphate (ADP) and adenosine triphosphate (ATP). The various nucleotides are essential in energetics and as co-factors in many reactions. The nucleotides may also form copolymers with other nucleotides, some of which must be of the pyrimidine type. These mixed polynucleotides or ribonucleic acids (RNA) have a large molecular weight and a structure not unlike that of proteins. They are as essential to life as proteins and there is good evidence to suggest that they may furnish the templates on which protein molecules are synthesized. There is another type of nucleic acid which is formed from the nucleotides of "deoxy" sugars. This is that of deoxyribonucleic acids (DNA) which are found only in the nuclei of cells and from which the chromosomes are made. The purines (and pyrimidines) needed for synthesis of nucleotides and nucleic acids are derived from the diet either as preformed compounds or as simpler molecules from which the body can synthesize these nitrogen-containing ring systems. This latter process is called *de novo* synthesis.

The human red blood cell contains large quantities of nucleotides, particularly ATP. It had occurred to various investigators that these compounds might be direct precursors of the urinary uric acid excreted by human beings. I have studied some of these relationships, taking advantage of the fact that blood is an unusual tissue in that it can be maintained outside the body for several hours. Under proper circumstances in vitro its metabolism seems to be essentially that seen in vivo. For example, an aliquot of freshly drawn blood can be extracted with trichloroacetic acid and its nucleotides fractionated on columns of Dowex-1 formate resin.[1] Another sample of blood may be incubated at body temperature, under a suitable gas mixture, and after two hours its nucleotides can be extracted and fractionated in an identical manner. The two nucleotide patterns will be similar. This is not true for other tissue such as muscle or intestinal mucosa. It is difficult to carry out incubation studies on such tissues, as well as to determine their in vivo distribution of nucleotides, since the pattern deteriorates rapidly even during the short time needed to remove the tissue from the animal and immerse it in trichloroacetic acid.

We have incubated human blood with radiocarbon (C^{14})-labeled, preformed purines and have found that some of these purines are readily incorporated into the blood nucleotides. For example, adenine was promptly incorporated into ATP, while guanine was incorporated into the analogous guanine nucleotide, GTP. There was little interconversion of the purines, however. Furthermore, the uric acid of the blood did not become appreciably labeled. This suggested that the blood nucleotides, although active metabolically, were not major sources of blood uric acid. Another series of studies demonstrated that C^{14}-tagged glycine could not be incorporated into the human blood nucleotides. This indicated that these highly specialized cells did not synthesize purines *de novo.* The blood from gouty subjects was also studied, with use of the same incorporation and fractionation techniques. It was hoped that this might reveal some marked metabolic abnormality, such as *de novo* synthesis, which could account for the pathogenesis of gout. The gouty blood behaved almost like the normal blood, except that the data were less consistent. This suggested poorer regulation of purine metabolism in the gouty blood but did not point to any specific defect.

The mammalian red blood cell is unusual in that it carries on virtually no respiration. It derives its energy mainly from glycolysis, but some also comes from oxidation of glucose by way of the hexose monophosphate shunt. This is also called the pentose phosphate pathway, because several pentoses, including those excreted in pentosuria, can arise through the reactions involved. The first enzyme in this pathway is glucose-6-phosphate dehydrogenase. Through it the oxidation of [illegible] coupled to the reduction [illegible] nucleotide (TPN). It is the reduced TPN which presumably keeps hemoglobin in the reduced (active) state. Congenital or drug-induced methemoglobinemia is probably related to malfunction of the shunt pathway. This pathway is also involved in favism and in primaquine sensitivity, since the susceptible persons lack adequate amounts of the enzyme glucose-6-phosphate dehydrogenase. Under these circumstances they are unable to maintain adequate levels of reduced TPN (and thence reduced glutathione) when they come in contact with certain noxious substances. The exact relationships between hemoglobin reduction and hemolysis are not entirely clear as yet. Perhaps more than one mechanism is operating.

The viable red blood cell maintains a high concentration of potassium inside and a high concentration of sodium outside. This is paralleled by a high concentration of ATP in the cell. As the cell becomes less competent, the potassium begins to leak out and the sodium in, and the ATP concentration falls. These changes are reflections of failing metabolism and of a decreasing store of energy. Thus, the viability of stored red blood cells at a given time can be assessed by measuring the amounts and types of nucleotides present. By this means it is possible to compare various blood storage systems in a more quantitative way.

We have observed the blood nucleotide patterns of blood collected in A. C. D. solution and incubated at 37 C for periods up to three days. The changes are progressive and furnish a scale on which to measure blood stored under other conditions. It will be necessary to relate the blood nucleotide content of transfused red blood cells to their fate in the recipient, since this is the criterion of success in transfusion.

The determination of blood nucleotides for clinical purposes is now only in the research stage because of the time and skill required; nevertheless, some correlations have emerged. We have noted, for example, that, in patients with terminal nephritis, the blood nucleotides are dramatically increased.[2] Gouty patients exhibit some of these increases, although to a lesser extent. This suggests altered kidney function in the gouty subject and raises the question whether the gouty subject has primary or secondary kidney damage.

Other reports in the literature suggest that in hyperthyroid persons the blood ATP concentration is decreased.[3] One interpretation of these findings is that thyroid hormone interferes with the production of ATP or causes its more rapid dissipation. Drugs such as dinitrophenol are known to "uncouple" oxidative phosphorylation, and their thyroid-like activity may help to unravel the true action of thyroid hormone. Another report offers preliminary evidence that under certain conditions radioactive phosphorus is incorporated into ADP more rapidly in the blood of the schizophrenic patient than in the normal human being. Confirmation and extension of this finding may give a clue to the etiology of this disease.

It is apparent that uric acid, a compound in which great clinical interest has been shown for the past several decades, now has many chemical "relatives," some of which may be equally exciting. In the foregoing remarks I have attempted to highlight a few of the many possible interrelationships in this area and to suggest that potential clinical-biochemical relationships are awaiting their cues so that they too may give a memorable performance.

SPECIAL CONTRIBUTION

The following statement presented by President John S. Millis, of Western Reserve University, who served as Chairman of the ad hoc *Advisory Committee to the Committee on Scientific Activities of the Board of Trustees of the American Medical Association at the meeting held at Hershey, Pa., Sept. 14-16, 1959, is a résumé of the conclusions reached by this group. The thoughtful, constructive nature of this résumé merits widespread reading and consideration, and it is for this reason that the report is being published in* THE JOURNAL.

EDWARD L. TURNER, M.D., *Director.*

CHALLENGES AHEAD

John S. Millis, Cleveland

My task as Chairman of the *ad hoc* Advisory Committee is to review the scientific activities of the American Medical Association to describe the forest of which the individual trees have been described by my colleagues reporting on the deliberations of the five sections. In doing so I wish to acknowledge the assistance of each member of the Committee who contributed. It was clear that the members of the Committee are conscious of the fact that this is the first such conference convened by the A. M. A., and in that sense it has been a revolutionary occasion—an occasion in which we are trying to see how revolutionary forces can be channeled to produce evolutionary changes. We feel that the opportunity to learn more about the organization of the A. M. A. and to meet with representatives of the Board of Trustees, the Councils, Committees, Departments, and the staff has been a valuable experience. We are particularly grateful for the material that has been prepared for us and for the contributions that the A. M. A. staff has made to our discussions.

It is quite apparent that the American Medical Association has been reviewing its program during the past several years. We see every evidence of a critical and self-analytical approach to this review and we applaud the attitude which lies behind it. The American Medical Association has played a vital role in the development of medical education and medical science in the United States. We are conscious of the role of the American Medical Association in leadership in the advancement of medical education as personified by its role in the Flexner report. Since that study the A. M. A. has maintained a role of aggressive leadership in maintaining high standards for medical education and for medical science. In our deliberations we have been continually conscious of this position and have only desired to assure maintenance. The rapid changes that have occurred in medical education and medical science in the United States, particularly since World War II, raise intriguing challenges to any organization which is concerned with the maintenance of standards. It is our observation that the American Medical Association has been mindful of this problem and has kept pace with advances. Thus, we are not concerned primarily with past accomplishments but rather desire to look to the future.

It is my belief that in our considerations we have had an image expressed as to the fundamental nature of the American Medical Association. We see it as the greatest force, if not the exclusive force, within the fabric of medicine which is concerned with supplying unifying forces to be the counteraction to those forces which divide medicine itself. I have heard the words "umbrella" and "funnel" used and have dared to use the analogy of a cable-twisting machine or some sort of a device wherein you may unify many disparate and sometimes conflicting interests, forces, and energies under one single entity. The Association, therefore, has the same fundamental problem as any other organization within a free society which endeavors in a complex age, fraught with divisive forces, to produce coherence and unity. In itself, therefore, it must always be conscious of this unifying or "umbrella" function, and in all that it does, programwise and organization-wise, this should be a paramount consideration.

Relevant Ideas

To present the aspect before us, I would like to advance five central ideas which we think are relevant to the thinking and the planning and the action of the Division of Scientific Activities of the A. M. A.

Report of the *ad hoc* Advisory Committee to the Committee on Scientific Activities of the Board of Trustees of the American Medical Association, Hershey, Pa., Conference, Sept. 14-16, 1959.

People for Medicine.—I have called the first idea "people for medicine." The central problem of any learned profession or of any activity in life is the assurance of enough of the right kind of people for the continuation and for the health of the profession. Therefore, we must be concerned about students, and it is difficult for the consultants to see how the American Medical Association can forego a deep concern about the number of students coming to our medical schools and their quality. Suggestions have been made about plans for recruitment, and sometimes we take the defensive point of view on the plea that other professions are actively recruiting and soliciting students, frequently with an offer of financial assistance.

Second, it is a constant responsibility of the A. M. A. to insure that the health of the American people is adequately cared for with enough practitioners sufficiently efficient to discharge their responsibilities.

Third, frequent reference has been made to the necessity for seed-corn—those members of the profession who serve their roles as teachers and as investigators and who insure the future because they dedicate their lives and their energies to the teaching and to the investigative phase of the total profession.

And, last, I would enumerate under the general heading of "people for medicine" the continuing necessity for communication—communication from organized medicine to the young people of America so that they will know what the profession is and what its opportunities and its glories truly are; communication from organized education through the secondary, collegiate, and the graduate level; and communication to the general public about the people, who, after all, are the fundamental resource and asset of medicine.

Education for Medicine.—My second heading is "education for medicine." I believe it to be true in the entire educational process that it really has no beginning except birth and no termination except death, or perhaps in some cases retirement. But it is particularly true in the learned profession—I would remind you that medicine is one of the oldest worthy of that description—where there is an entire spectrum beginning with secondary education running through premedical preparation, through the full-time occupation of the student and the M.D. program, through the full-time occupation in the internship and residency, and through part-time occupation in continuing educational activities. This is a fragmented responsibility—part carried by secondary schools, part by colleges, part by medical schools, part by hospitals, and part by various associations and agencies in the continuing educational phase. No one in any organization is in so valuable and so central a position as to see the entire sweep of the educational process and to assume the responsibility for coordination and for relationship of that important thing which is education in medicine.

It should be pointed out, I think, in this connection, that since education is a vast sweep, when we think about the problems of support for education for medicine we cannot think in isolation about the needs of any single segment thereof but rather the entire spectrum of the process and the continuing process of education for medicine. Perhaps I might use this analogy: some foolish householder might be concerned exclusively with the condition of his house above the foundation line. He might spend vast sums in painting the exterior, in insuring the soundness of the plumbing or the weather-tight character of the roof, and fail to pay attention to the state of the foundation. I think the analogy is valid, for if medicine is concerned only about medical education as we normally think of it in the medical school or in the hospital, we are blind indeed, for the health of medical education is no greater than the total educational enterprise. As an example, unless the A. M. A. Division of Scientific Activities is as concerned about the sciences of chemistry, biology, physiology, and biochemistry as it is about the departments of surgery, psychiatry, pediatrics, and medicine, then it is neglecting an integral part of the total structure.

Interprofessional and Intergroup Relations in Medicine.—Third, I would direct your attention to the general heading of "interprofessional and intergroup relations in medicine." Medicine is fragmented. It is fragmented by specialization, but specialization is an absolute necessity; we shall have more of it and it shall be more intense. The physician will continue to be served by a vast array of groups in areas allied to medicine as he tries to multiply his effectiveness and his efficiency by having the assistance of many, many kinds of persons. Therefore, the relationship of these groups in areas allied to medicine—of specialty groups, of the teacher to the practitioner, the practitioner to the investigator—is of prime importance. The A. M. A. is the one organization which can do the most and, therefore, must carry the largest responsibility. In this might I express the hope that the A. M. A. would see this as a challenge and opportunity for a positive approach; for the A. M. A. must invite the interest and the association of these other groups. You cannot command it and they, being human, probably will not offer it voluntarily. There are perhaps things which the A. M. A. may do positively. One suggestion, which has not been made as a recommendation but is indicative of the thinking of some members of our group, concerns the idea of a group of medical scientists, advisory directly to the Board of Trustees, as an avenue by which the hopes, aspirations, goals, desires, and dreams of the medical scientists could be communicated directly to the top responsible body of the Association.

Inquiry for Medicine.—My fourth topic is "inquiry for medicine." I use the word inquiry rather than research or investigation because I think it includes both of those and more. As to the specific idea of research, Dr. Simeone, I think, has voiced the thinking of all of us that this is an area in which many other agencies are engaged and in which they have greater competence and greater skill, experience, and facilities than the A. M. A. has or could ever possibly have. This, on the other hand, does not mean that the A. M. A. does not have a responsibility and should not take the position of aggressive leadership. There is always the function of the review of research, the searching to identify and to see that gaps are filled in the whole process of medical research. There are various areas of direct inquiry—direct inquiry into the standards of medical care. As a university president, I am always conscious of the fact that when I try to exercise judgment on the recommendations of my colleagues of the faculty as to how medical education should be conducted, I do not have an authoritative and comprehensive statement from any competent and authoritative source as to what good medical care is, thereby to judge what good medical education shall be.

Another area of inquiry has been suggested, namely, some measurement of what it is that the practicing physician desires and needs in the field of continuing education. Hence, under the heading of inquiry for medicine, I would remind you of the evaluative function, the continual need for someone, some agency, or some organization to try to distill wisdom from information and knowledge from the compilation of statistical data. This function the A. M. A. is doing in the standards maintained for its journals, but it is a continuing responsibility.

Last, I would emphasize that single thread which runs through all of this, namely, the necessity for communicating ideas and thoughts and information and knowledge and, yes, even wisdom. This is something which an organization that assumes responsibility for providing coherence and unity cannot possibly escape. Communication in the field of inquiry, whether it be research or investigation is of fundamental and significant importance.

Philosophy of Organization for Medicine.—Fifth, I would mention philosophy of organization for medicine. If our image of what the A. M. A. wishes to be, is, and shall be in the future is correct, namely, a unifying force, then it seems to me that it follows directly and logically and inescapably that in the organizational techniques which the A. M. A. adopts to carry out its responsibilities, it must always and ever be careful to see that its organization is not divisive but always unifying. If we adopt the easy way of meeting problems by the organization of one more Division and one more Council as a universal technique, then we are introducing additional divisive forces and not doing what the A. M. A. wishes to do, namely, to provide unifying devices. It was for this reason that Group D, of which I was a member, spent so much time and I think emphasized so heavily the necessity of thinking about the organization of the Division of Scientific Activities in terms of universality with common techniques for the solution of problems—temporary, ephemeral, or long-term as they may be—and suggested that there is some merit at least in thinking about the possibility of an organization which reflects the common element and the uniting elements in this particular task.

Summary and Comment

May I now add a personal note, and I think I echo again the sentiments of all who have come here at your kind invitation—a sense of pleasure and a thankfulness for the opportunity of being together and trying to come to grips with knotty problems, but above all a sense of participation in a high adventure—the adventure of a group of men and women resolved to do a job against a background of freedom and liberty, of trying to meet the complex problems of our society with that context and upon those assumptions. The word which I would underscore and ask the A. M. A. always to have in its mind is that it is a *voluntary* association and that which is done is not done by the decisions of dictators or a single group of men or women but, rather, by the voluntary decision of a group of free men deciding that which is wise, prudent and moral, and thereby adjusting their own desires and needs, hopes and ambitions, and sometimes even their own economic circumstances, that this high purpose may be accomplished.

I hope that as the prosecution rests the case, at least as the *ad hoc* Committee rests its case, that we have perhaps accomplished something in response to your kind invitation.

ACUTE PERIPHERAL ARTERIAL EMBOLIZATION

GUEST EDITORIAL

Richard W. Egan, M.D.

THE acute occlusion of a peripheral artery by an embolus poses a difficult problem in management for the internist and surgeon alike. The immediate mortality is disturbingly high. In this issue of THE JOURNAL, page 799, Goldowsky and Bowen report an immediate mortality of 37% in their series of 46 embolectomies in 42 patients. Andrus,[1] in 57 instances of peripheral arterial emboli treated without surgery, noted an immediate mortality of 32%. Rosenberg and associates[2] recently reported an immediate mortality of 10% after arterial embolectomy. Goldowsky and Bowen were able to obtain follow-up information on the 25 patients who survived the initial embolus. In this group there were nine late fatalities, and all but one could be attributed to cardiovascular disease.

The patient presenting with an acute occlusion of a peripheral artery poses a dual problem. The underlying cardiovascular disease from which the embolus arose is frequently of serious life-threatening proportions. These patients most commonly have rheumatic heart disease with abnormalities of cardiac rhythm, coronary artery disease with myocardial infarction, or extensive arteriosclerotic cardiovascular disease. The number of immediate and late deaths in this group of patients is for the most part directly proportional to the severity of their cardiovascular disease. The acute arterial occlusion is mainly a threat to the survival of the affected extremity, although it may contribute materially to the death of the patient. The consequences of acute embolic arterial occlusion vary with a number of factors. Occlusion of the anterior or posterior tibial artery of the leg or the radial or ulnar artery of the forearm often results only in transient pain and weakness of the extremity. On the other hand, practically all patients with a saddle embolus obstructing the bifurcation of the abdominal aorta will die if untreated. The ultimate effect of the occlusion of the arterial supply to an extremity is influenced by a number of factors. The survival or viability of the extremity distal to the occlusion is dependent on its collateral arterial supply. If this network is sufficient, the extremity will survive, although the sequelae of chronic arterial insufficiency may be anticipated. When marked proximal vasospasm and distal propagation of the clot is associated with the acute embolus, the collateral circulatory bed is impaired and progressive ischemia leading to necrosis will ensue.

There are three problems that confront the physician when caring for a patient with an acute peripheral embolic arterial occlusion, namely, the disease entity which caused the embolus, the arterial circulation of the affected extremity, and the prevention of subsequent embolic episodes. In that the deaths in these patients can frequently be attributed to the severity of their chronic cardiovascular disease and its progression, this should receive primary consideration in the treatment of the patient. If surgical embolectomy is contemplated one has time to evaluate the general status of the patient, particularly from the cardiovascular standpoint, and institute the indicated therapeutic measures. Furthermore, one has time to observe the effect of nonoperative therapeutic measures, such as sympathetic ganglion block or intra-arterial vasodilating agents, on the arterial circulation of the affected extremity. The acute occlusion is an immediate threat to the viability and survival of the affected limb. If sufficient collateral circulation is present to assure viability of the tissues distally, especially in the presence of serious decompensated heart disease, conservative nonoperative therapy aimed at augmenting the collateral arterial flow and preventing the propagation of the clot will often suffice. In view of the advancements in vascular surgery it is possible to ameliorate or correct the resulting chronic ischemia at a later time under less adverse circumstances. When the embolus is lodged in a major vessel with marked peripheral ischemia and insufficient collateral arterial flow, then a care-

[2] Rosenberg, J. C.; Emerson, E. C.; and Murphy, T. O.: Clinical Study of Embolectomy, Angiology 8:371-377 (Oct.) 1957.

fully planned and executed surgical embolectomy to establish a more normal arterial flow is mandatory to increase the limb salvage rate. The high attrition after successful management of such an episode and the number of patients who have subsequent embolic phenomenon makes it necessary that intensive long-term preventative measures be instituted. This may mean valvuloplasty in some and probably long-term anticoagulant therapy in most patients.

Only by a combination of intensive medical therapy of the underlying disease, careful selection of patients for surgical embolectomy, and intensive, diligent, and prolonged preventive measures in the postembolic period will the immediate and late mortalities be reduced and the limb salvage rate increased. In the future the addition of human fibrinolysin for the dissolution of fresh thrombi may be a worthwhile addition to our therapeutic armamentarium.

URIC ACID SECRETION AND EXCRETION

The course that uric acid (urate) follows through the kidney has been the object of investigation since the development of techniques of the study of this function. The best evidence advanced a generation ago, in the golden age of physiology, suggested that plasma uric acid is completely filtered through the glomerular membrane, that a significant proportion of the filtered substance is reabsorbed by the tubules, and that none is excreted through active enzymatic mechanisms or by differences in osmotic pressure between the tubules and circulating blood. A. N. Richards, of the University of Pennsylvania School of Medicine, and Homer W. Smith, of New York University College of Medicine, were staunch proponents of this mechanism. Their conclusions were supported by the best experimental data available at that time produced by the best techniques that had been devised.

It was important to place reliance on a sound concept of the mechanism of exchange of uric acid in any consideration of the pathogenesis of gout. An acceptable working or proved hypothesis of renal exchange was vital to the explanation of the increased concentration of uric acid in blood and body fluids—a consistent abnormality in patients with gout. An increased concentration of plasma uric acid could be related to (*a*) impaired destruction resulting from a deficient enzyme system, (*b*) increased production of uric acid resulting from an overly active enzyme system or from a shunt mechanism in the intermediary metabolism of this substance, or (*c*) an abnormality in the renal excretion of uric acid resulting from either impaired filtration by the glomerular membrane or altered excretion through the tubules.

The destruction of uric acid in patients with gout is not an attractive hypothesis, nor has any laboratory evidence been produced to support this mechanism. The polemic over the years has been waged concerning the second and third possibilities. A limited number of patients with gout excrete abnormally large quantities of uric acid in the urine. Investigation by isotope techniques of another segment of the gouty population reveals an overproduction of uric acid. There remains yet a third segment of those afflicted with gout who reveal neither defect. The clinical findings of articular gout and an increased concentration of uric acid in the serum leaves no doubt about the diagnosis. The failure to discover a satisfactory etiological mechanism in this group has prompted reexamination and restudy of the renal exchange of uric acid in gouty and nongouty persons.

Studies of this function have been reported recently from two laboratories. Gutman and associates,[1] at the Mount Sinai Hospital in New York, presented experimental data in support of the mechanism of tubular secretion of uric acid in the normal as well as the gouty person, a reversion to the Heidenhain theory of renal exchange of solutes. Gutman's observations have led him to an additional premise, i. e., under normal circumstances, the uric acid excreted from the kidney and into the bladder is largely derived by tubular secretion. Nugent and Tyler,[2] of the University of Utah School of Medicine, administered urate precursors orally to nongouty subjects in order to increase their plasma uric acid concentrations to the range found in patients with gout. Under these conditions the urate clearance and urate excretion rates achieved in nongouty subjects were well above those observed in the gouty patients. Nugent and Tyler concluded that abnormal renal excretion of uric acid is one important cause of hyperuricemia in some patients with gout. Secretion of uric acid by the renal tubule seems likely on the basis of the investigations pursued in these laboratories, widely separated geographically.

It is reasonable to assume at present that the pathogenesis of gout may be a function of several metabolic abnormalities and may not be confined to a single defect. An increased formation of uric acid contributes heavily in some patients with gout; in others there may be an abnormal renal exchange to account for the increased concentration of uric acid in body fluids. All or a portion of the uric acid that appears in the bladder urine may be the result

2. Nugent, C. A., and Tyler, F. H.: Renal Excretion of Uric Acid in Patients with Gout and in Nongouty Subjects, J. Clin. Invest. 38:1890-1898 (Nov.) 1959.

of secretion by the tubules and not the residual of reabsorption of filtered urate. Secretion of uric acid by the tubules also provides a satisfactory explanation for the hyperuricemic effect of two drugs, pyrazinamide and chlorothiazide, useful therapeutic agents with a hyperuricemic side-effect quite unrelated to their desirable therapeutic features.

The alteration in emphasis on the etiological mechanisms responsible for the changes observed in gouty patients does not modify the recommendations for treatment. The prophylactic value of colchicine and a potent uricosuric agent remains good. These drugs are practical and effective in the prevention of recurrences of acute articular distress.

AN OUTSIDER SPEAKS

Formal education in America has been fortunate over the years in attracting a select number of physicians to the post of president or chancellor of some of our great universities. The promotion to the top rung of the academic ladder has been through the deanship of the medical school in some instances; in other schools the advancement has been from the headship of a clinical or basic science department. From whatever source the talent is sought, performance has been notable and the university has reaped the reward of outstanding leadership. The majority of university presidents, however, have not been medically trained and have had no choice but to learn by conference and contact in a relatively short time about this one division of the university which is unique and different from all of the others. An example of uniqueness is the annual budget.

The financial burden imposed by a medical school on the parent university is a critical item that no university president can pass by readily. In return, the stature of the medical school and the enhancement thereby of stature of the university is an ill defined but highly desirable investment that no president dares ignore. Indeed several outstanding universities in America are better known for the medical schools in the eyes of the public than for any other department, fine as the other departments may be. Western Reserve University, an institution of higher learning, supports an excellent medical school as well as an excellent university in the broad sense of the term. John S. Millis is the president.

President Millis participated in the Hershey, Pa., conference which was held under the Division of Scientific Activities of the A. M. A. This was a notable conference and attracted many outstanding leaders in medical and liberal education in America. Several of the contributions have appeared in The Journal. In this issue a summary of the deliberations of the *ad hoc* Advisory Committee of the conference is published. The exposition by President Millis is clear, penetrating, and thoughtful. The position of the American Medical Association in medicine for tomorrow is presented imaginatively but not extravagantly, and no promise is offered that cannot be achieved if proper forces are permitted to operate. President Millis was not medically trained. There is no doubt, however, of his ability to comprehend the problems that face American medicine and how best to reach the goals that lie ahead.

This report is recommended reading. The conclusion bears repetition: "——a sense of participation in a high adventure—the adventure of a group of men and women resolved to do a job against a background of freedom and liberty, of trying to meet the complex problems of our society with that context and upon those assumptions. The word which I underscore and ask the A. M. A. always to have in its mind is that it is a *voluntary* Association and that which is done is not done by the decisions of dictators or a single group of men and women but, rather, by the voluntary decision of a group of free men deciding that which is wise, prudent, and moral—and thereby adjusting their own desires and needs, hopes and ambitions, and sometimes even their own economic circumstances, that this high purpose may be accomplished."

THE CONFERENCE

In effect, the conference has become, the world over, a substitute for the work. That is its appeal. Take at any instant a census of the great talents of the world and you will find the large proportion preparing, attending, or recovering from a conference. When you add to the burden of the physical event itself the mass of ancillary paper work required, from the preparatory letter writing to the transcripts of discussions that nobody reads (except to correct his own stammerings before publication), you may conclude that here make-believe reaches its apogee.—J. Barzun, The House of Intellect, New York, Harper, 1959.

CHANGE OF ADDRESS

If you change your address please notify The Journal at least six weeks before the change is made. DEPARTMENT OF ECONOMIC RESEARCH

"THE CONSTITUTION OF LIBERTY"

Arthur Kemp, Ph.D., Chicago

It is a unique privilege and a delight to read for the first time a time-tested classic; it is an even rarer privilege to recognize a great book when first it is published. Such is "The Constitution of Liberty,"[1] intended to be published 100 years to the day after the first appearance of John Stuart Mill's essay, "On Liberty."

Fifteen years ago Professor Hayek warned eloquently of the trend of human events in western civilization in a volume entitled "The Road to Serfdom." Phenomenally successful, its impact on liberal thought can be credited with having dealt a mortal blow against the socialism then growing in England. Professor Hayek has now developed more fully a system of political and social thought dedicated to liberty and based on the thesis that only through liberty can the spirit of civilization survive. It provides the most significant contribution in the 20th century to a restatement of the principles of a free society on which the growth and even the survival of western civilization depends. It is not merely a statement of faith, although Professor Hayek's faith in freedom is apparent despite his conscious and evident attempt to bend over backward in avoiding the emotional connotations frequently associated with the terms freedom and liberty.

"The Constitution of Liberty" is a philosophical treatise consisting of three parts. The first concerns itself with the basic issues and values of liberal political and economic philosophy. The second describes the development of those institutions of western civilization that, up to the present, have helped to establish a relatively high degree of individual liberty; essentially it is a historical description of the development of classical liberal jurisprudence. The third part tests the principles espoused in the first part and the institutions described in the second by applying them to some of the critical economic and social issues of our times.

So far as basic philosophy is concerned, perhaps the most significant appeal to the medical profession is Professor Hayek's explicit recognition of the boundless variety of human nature, of the infinite variety of individual attributes, and of the wide range of differences in the capacities and abilities of individual human beings. This is the biological and, hence, medical cornerstone on which "The Constitution of Liberty" rests.

There are also passages of great interest to the medical profession in its current struggle against attempts by government to coerce and control that profession and the financing of medical care. Chapter 19 deals with the relationship of the principles of liberty to the problem of what is called social security, including provision for old age, unemployment, and sickness. Professor Hayek clearly recognizes that the term "social insurance" is in fact a misnomer. He points out that "from the beginning, it had little to do with insurance and has since lost whatever resemblance to insurance it may ever have had" (p. 289). He also warns with vigor of the dangers inherent in acceptance of the value judgments of the new expert in a particular institutional setup, who is, by definition, an expert simply because he is in favor of current trends in policy. This danger, Professor Hayek thinks, is particularly important in such areas as social security systems, housing, education, and, as a matter of fact, the entire social service bureaucracy. Wisely he points out that "this is indeed one of the factors which tend to make so many contemporary developments self-accelerating. The politician who, in recommending some further development of current policies, claims that 'all the experts favor it,' is often perfectly honest, because *only those* who favor the development have become experts in this institutional sense, and the uncommitted economists or lawyers who oppose are not counted as experts" (p. 291).

Another fundamental principle on which Professor Hayek's treatise rests is the recognition of the debt man owes to the developments that have taken place beyond conscious social control, developments that are the result of spontaneous forces of growth, that were unknown and perhaps unknowable. Hayek believes that the advantages of a free civilization have rested in the past, at least in part, on man's inability to control completely his social life; he is concerned lest, with a greater variety of controls within his power, man may hesitate to permit spontaneous development and perhaps may even discourage it by the use of controls, when in fact continued advance depends on his deliberately fostering spontaneity. "In the past," says Hayek, "the spontaneous forces of growth, however much restricted, could usually still assert themselves against the organized coercion of the state. With the technological means of control now at the disposal of government, it is not certain that such assertion is still possible; at any rate it may soon become impossible. We are not far from the point where the deliberately organized forces of society may destroy those spontaneous forces which have made advance possible" (p. 38).

This principle is recognized again and again throughout the book, perhaps nowhere more clearly than in the field of social insurance and, more particularly, health insurance. Hayek recognizes that governmental health insurance schemes have almost inevitably involved the development of a single-track government authority. The development of insurance was not dependent on the discovery of any single man or group of men; but the insurance principle evolved over time in a way that no man ever aimed at and no group of men created. His eloquent warning against state monopoly in these developments (p. 292) is as follows:

> Significantly enough, in the two main fields which the state threatens to monopolize—the provision for old age and for medical care—we are witnessing the most rapid spontaneous growth of new methods wherever the state has not yet taken complete control, a variety of experiments which are almost certain to produce new answers to current needs, answers which no advanced planning can contemplate. . . . To make the best available knowledge at any given moment the compulsory standard for all future endeavor may well be the most certain way to prevent new knowledge from emerging.

It might be an act of statesmanship as well as one of self-preservation to send marked copies of this book to all those members of Congress who are concerned with such legislative proposals as seem determined to halt the continuing development of private insurance in answer to health problems.

Hayek recognizes that it is not impossible to develop governmental allowances and social subsidy systems into systems of true insurance. He doubts, however, that there is as much to be obtained in this way as from those offered by competitive institutions and constant experiments with new ways of settling the questions.

Chapter 17, entitled "The Decline of Socialism and the Rise of the Welfare State," should be of great help to the members of the medical profession in understanding why it is much more difficult today to fight certain concepts of socialized medicine than it was when the attempt was being made to develop a complete and definite program of a new socialist society. Hayek believes the Marxist experience in Russia and the Socialist experience in Britain and elsewhere has brought about an abandonment of the traditional Socialist program. But, at the same time, this makes more difficult a defense against particular unsystematic collectivist actions that in and of themselves can be dressed up in very fetching garb. Even the attempt to designate such developments as the "welfare state" will not help since it is not in fact a recognized, organized system of thought. The defense of liberty is much more difficult when it is opposed by individual programs unconnected one with the other, such as Forand-type legislation and the like, than it is when the avowed purpose is to tear up the roots of existing society to establish a new one. The new, uncoordinated, piecemeal attack of the welfare state uses national coercive power "to insure that particular people get particular things, . . . a kind of discrimination between, and an unequal treatment of, different people which is irreconcilable with a free society . . . It is bound to lead back to socialism and its coercive and essentially arbitrary methods" (pp. 259-260).

One paragraph ought to be read by every member of the medical profession; indeed, by every member of every profession, and certainly by every statesman and politician. Hayek expresses it (p. 300) as follows:

> There are so many serious problems raised by the nationalization of medicine that we cannot mention even all the more important ones. But there is one the gravity of which the public has scarcely yet perceived and which is likely to be of the greatest importance. This is the inevitable transformation of doctors, who have been members of a free profession primarily responsible to their patients, into paid servants of the state, officials who are necessarily subject to instruction by authority and who must be released from the duty of secrecy so far as authority is concerned. The most dangerous aspect of the new development may well prove to be that, at a time when the increase in medical knowledge tends to confer more and more power over the minds of men to those who possess it, they should be made dependent on a unified organization under single direction and be guided by the same reasons of state that generally govern policy. A system that gives the indispensable helper of the individual, who is at the same time an agent of the state, an insight into the other's most intimate concerns and creates conditions in which he must reveal this knowledge to a superior and use it for the purposes determined by authority opens frightening prospects. The manner in which state medicine has been used in Russia as an instrument of industrial discipline gives us a foretaste of the uses to which such a system can be put.

If there were but one nonprofessional book every doctor could read in the year 1960, this ought to rank high on the list. It deals with the basic problems of freedom that are of paramount importance not only to medicine but to each and every person. Moreover, it will aid the members of the medical profession, and indeed all of us, to understand that the benefits of freedom are not confined to the individual doctor or to the medical or any other profession. We derive the greatest benefits not because we are free but because others are free. To recognize this is essential to an understanding of the nature of a free society and the benefits to be derived therefrom. Above all, in the struggle to survive in the war of ideas, we must recognize this principle as fundamental to our own position lest, as the saying goes, "we manage to snatch defeat even from the jaws of victory."

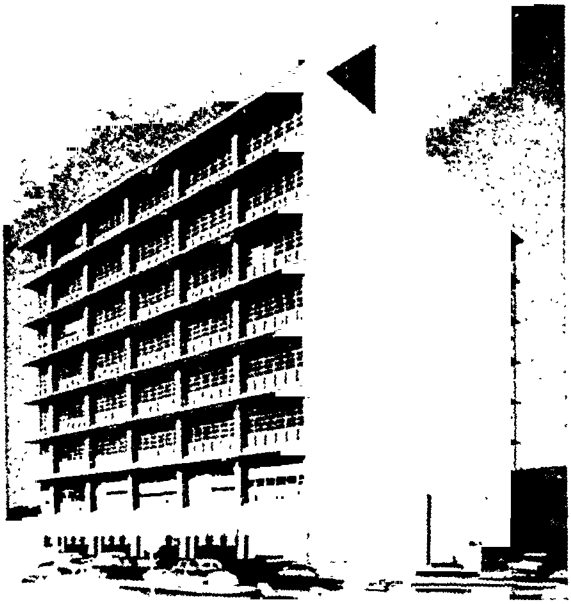
MEDICAL NEWS

DISTRICT OF COLUMBIA

Mental Health Bureau Appointments.—The Government of the District of Columbia, Department of Public Health, announced that on Jan. 4, Dr. David A. Lanham and Dr. Irving L. Berman joined the staff of the Legal Psychiatric Services Division. Dr. George Chornesky was appointed acting chief, Alcoholic Rehabilitation Division, effective Jan. 11, succeeding Dr. Jean H. Menetrez, who will continue to work with the bureau as staff psychiatrist in the Adult Mental Health Division on a part-time basis.

FLORIDA

Research Building to Be Dedicated.—The University of Miami School of Medicine will dedicate its new research building on March 3 in an outdoor ceremony at the Medical Center in Miami. The building, nine stories high and containing 90,000 square feet of space, provides laboratory facilities for all departments of the school. Construction took 18 months, and funds were obtained from the U. S. Public Health Service, from Dade County (Fla.), and from university sources. Dr. Robert B. Lawson, chairman, department of pediatrics, is general chairman for the dedication program; Mr. Hoke Maroon, Miami banker and president of the medical school council, is co-chairman. Guided tours through the building will be sponsored for civic and professional groups as well as for the general public.



University of Miami School of Medicine Research Building (university photograph by David Greenfield).

IDAHO

Cancer Conference in Boise.—The American Cancer Society, Idaho Division, will hold its annual cancer conference April 1-2 at the Hotel Boise, Boise. The program includes the following participants: Dr. John L. McKelvey, Minneapolis; Sol Silverman Jr., D.D.S., San Francisco; Dr. Murray M. Copeland, Washington, D. C.; Dr. Ian G. MacDonald, Los Angeles; Dr. Michael B. Shimkin, Bethesda, Md.; and Dr. Walter C. Lobitz Jr., Portland, Ore. Informal luncheon discussions will be held the afternoon of April 1. Dr. Shimkin will be the guest speaker at the dinner 7:30 p. m., April 1, presenting "Medical Mission to Moscow." Two panel discussions are planned, one each day.

KENTUCKY

New Health Building in Frankfort.—The State Department of Health's new home in Frankfort—the McCormack Memorial Health Building—was dedicated on Dec. 6. The ceremony honored a father and son whose combined services as Kentucky's first two health commissioners covered 64 years. They were Dr. Joseph N. McCormack, who became the state's first health commissioner in 1878 and served until 1912, and Dr. Arthur T. McCormack, who succeeded his father and was in office until his death in 1943. Governor A. B. Chandler was the speaker at the dedication. Dr. Russell E. Teague, Louisville, present commissioner of health, presided. The new building, scheduled for completion in February, was built at a cost of $2,750,000. It is so designed that two more floors can be added.

MARYLAND

Hospital Program to Celebrate Relocation.—On April 24, the medical staff of the Sinai Hospital, Baltimore, will celebrate the relocation of its quarters by holding a scientific meeting at the new hospital. The program includes presentations by the following: Dr. Edward C. Curnen Jr., Chapel Hill, N. C.; Dr. Clarence Dennis, New York City; Dr. Saul J. Farber, New York City; Dr. Louis M. Hellman, New York City; Dr. Simon Koletsky,

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

Cleveland; Dr. J. Stauffer Lehman, Philadelphia; Dr. Morton L. Levin, Buffalo, N. Y.; Dr. Irving M. London, New York City; and Dr. Franz Reichsman, Rochester, N. Y. Recently the hospital was moved from its original site in Southeast Baltimore to a new site in the Northwest section of the city. The new facility contains an increased number of beds and bassinets, including 119 ward beds, larger quarters for the School of Nursing, and an outpatient department designed to handle up to 100,000 visits per year. Residence buildings for nurses and house staff adjoin the hospital. A three-floor research building has been provided.

MICHIGAN

Researchers Win Psoriasis Award.—The department of dermatology, Baylor University College of Medicine, Houston, Texas, announced that Isadore A. Bernstein, Ph.D., Walter D. Block, Ph.D., Dr. Espey F. Cannon, Herbert H. Cornish, Ph.D., Dr. Arthur C. Curtis, and Dr. Walker A. Lea, of the department of dermatology, University of Michigan, Ann Arbor, have been awarded the third annual Mr. and Mrs. J. N. Taub International Award for Research in Psoriasis. The $1,000 award was given for their research presented in a series of papers published in the *Journal of Investigative Dermatology*, "Nitrogen Balance and Sulfur Excretion Studies in Psoriasis," "Serum Uric Acid Levels in Psoriasis," and "Distribution of Lipids and Free Amino Acids in Psoriatic Scales." This award was established by Carol and Henry J. N. Taub in honor of his grandparents.

MISSOURI

Dr. Moore Lectures.—The 13th Jack H. Tritt Memorial Lecture of the Jewish Hospital of Saint Louis was given Feb. 4 by Dr. Carl V. Moore, Busch Professor of Medicine and chairman of the department of medicine, Washington University School of Medicine, entitled "The Metabolism of Iron."

NEW YORK

Course on Electron Microscope Techniques.—A special summer laboratory course in techniques and applications of the electron microscope will be offered to qualified senior biologists and medical research workers under the direction of Prof. Benjamin M. Siegel at Cornell University's Electron Microscopy Laboratory. The session will run from June 13 through July 1. The course will include laboratory work, lectures covering the basic principles and methods, and lectures on specific biological applications to be given by guest lecturers. It is being sponsored by a grant from the National Science Foundation. Requests for information and applications should be addressed to Professor Siegel at Rockefeller Hall, Cornell University, Ithaca, N. Y.

New York City

Symposium on Chronic Alcoholism.—The National Vitamin Foundation, Inc., announced that on March 1 the annual meeting and symposium, "Complications of Chronic Alcoholism—Their Causes, Management and Prognoses," will be held at the Hotel Pierre. The morning session, which will be given over to discussion of the central nervous system complication of alcoholism, will be chaired by Dr. Joseph M. Foley, chairman, department of neurology, Seton Hall University College of Medicine. Dr. Charles S. Davidson, Thorndike Memorial Laboratory, Boston City Hospital, will be chairman for the afternoon discussion of the hepatic complications of chronic alcoholism. For information, write the National Vitamin Foundation, Inc., 149 E. 78th St., New York 21.

Personal.—Dr. Blaise A. Pasquarelli, psychiatrist, received a Fordham Alumni Association Award at the association's 106th annual dinner Jan. 26. The awards are given to alumni "for winning distinction for themselves and for their college through their professional accomplishments." Dr. Pasquarelli teaches psychiatry at the Columbia University College of Physicians and Surgeons and is doing research on "Psychoanalysis and Religion" and "Unexplored Sources of Anti-Semitism."——Dr. Alfred P. Fishman, associate professor of medicine, Columbia University College of Physicians and Surgeons, was elected a member of the board of directors of the New York Heart Association. Dr. Fishman has been chairman of the Scientific Program Committee of the association since 1957.——Dr. S. Charles Franco was recently appointed executive director of the medical department, Consolidated Edison Company of New York, Inc. Dr. Franco is a member of the board of directors of the Industrial Medical Association and is also associate professor of industrial medicine at the New York University-Bellevue Medical Center.

OHIO

Annual Anesthesiology Address.—Dr. Julius H. Comroe Jr., of the Cardiovascular Research Institute, University of California Medical Center, will be the guest speaker at the fourth annual Rolland J. Whitacre Memorial Address sponsored by the Cleveland Society of Anesthesiologists. This will be a dinner meeting at the Wade Park Manor Hotel, Cleveland, on Wednesday, March 9. For reservations, contact Dr. June A. Dvorak, secretary-treasurer, 2235 Overlook Rd., Cleveland Heights 6, Ohio.

List of Scientific Periodicals.—The Cincinnati Chapter of the Special Libraries Association has published a new Union List of Scientific and Technical Periodicals of the Libraries of Greater Cincinnati and Vicinity which is available for sale. The

Union List covers the holdings of 35 libraries to January, 1958. Orders for copies should be sent to Roberta Andrews, U. S. Public Health Service, Occupational Health Field Headquarters, 1014 Broadway, Cincinnati 2. Cost per copy, $10, is payable to the Special Libraries Association, Cincinnati Chapter.

Personal.—The Cleveland Clinic announced the appointment of Dr. Wallace B. Hamby to the staff of the department of neurological surgery. Dr. Hamby will assume his clinic duties July 1 after completion of the academic year at the University of Buffalo Medical School, where he has been professor of neurological surgery since 1941.——Governor Michael V. DiSalle reappointed Dr. Ralph E. Dwork, Columbus, associate professor of preventive medicine at Ohio State University, as director of of the Ohio Department of Health, effective Nov. 8. Dr. Dwork, first appointed in 1954, will again serve a five-year term.

OKLAHOMA

Outbreak of Diphtheria.—The Oklahoma Health Bulletin for January reported that a 10-year-old Chickasha boy was the first death of six diphtheria cases which occurred in a two-week period. A 52-year-old Boswell woman and a 16-year-old Kingston girl also died. In Vinita a boy, 6, recovered, and in Owasso a 16-year-old girl is recovering. A 3½-year-old boy and 33-year-old woman, both of Oklahoma City, reported as cases had not been confirmed. As of Dec. 15 cases in Oklahoma numbered 11 for the year. Dr. Grady F. Mathews, commissioner of health, said "So far we have sent out enough toxoid of various kinds to immunize 27,155 persons. It has gone to Chickasha, Stillwell, Hugo, Pauls Valley, Anadarko, Ponca City, Blackwell, Guymon, Idabel, Watonga, Duncan, Elk City, Pryor, Okmulgee, Dewey, Lawton, Eufaula, Madill, Jay, Vinita, Ardmore, Tishomingo, and Oklahoma City."

GENERAL

Executive Director for Health News Institute.—The appointment of Mr. Marc Woodward as executive director of the Health News Institute was announced by Dr. Austin Smith, president of the organization. The institute has offices at 60 E. 42nd St., New York 17. Dr. Smith, Washington, D. C., president of the Pharmaceutical Manufacturers Association, said Mr. Woodward succeeded Mr. Chet Shaw, who resigned. Mr. Woodward has served as assistant executive director of the HNI since 1956, when the institute was organized.

Grants Available for Blindness Research.—The Research Committee of the National Society for the Prevention of Blindness invites requests for research grants in 1960. Funds are available for projects that may "contribute to basic understanding of eye function and pathology, or that may improve methods of diagnosis, treatment, or prevention of blinding eye diseases." Grants will be made this spring for requests received by April 1. Inquiries may be addressed to Research Committee, National Society for the Prevention of Blindness, 1790 Broadway, New York 19.

Medical Genetics Course.—A short course in medical genetics (Heredity and Disease in Man and Animals) will be conducted at Bar Harbor, Maine, Aug. 8-20, by members of the faculty of the Johns Hopkins University School of Medicine, Baltimore, and the staff of the Roscoe B. Jackson Memorial Laboratory, Bar Harbor. Forty participants can be accommodated. The course is designed primarily for persons in medical teaching and research. Information can be obtained from the co-directors of the course: Dr. Victor A. McKusick, Johns Hopkins Hospital, Baltimore 5, and John L. Fuller, Ph.D., Roscoe B. Jackson Memorial Laboratory, Bar Harbor, Maine.

Fellowships for Connective Tissue Research.—The Helen Hay Whitney Foundation announced that fellowships are available to any qualified person in the United States or abroad, up to the age of 25, holding the degree of M.D., Ph.D., or equivalent, who is seriously considering a career in biological or medical research, preferably relating in some way to connective tissue and its diseases. Fellowships are annual, subject to renewal consequent to good performance for a period of three years. The stipend is $6,000 a year, plus $500 for each dependent. Applications must be received on or before Aug. 15. Address inquiries to the Helen Hay Whitney Foundation, 525 E. 68th St., New York 21.

Report on Accidents.—More people died in accidents in 1959 than in the preceding year, it is reported by statisticians of the Metropolitan Life Insurance Company. Accidents took about 91,500 lives in continental United States last year, the statisticians estimate. However, the accident death rate, reflecting the increase in population, declined fractionally for the fourth year in a row to an all-time low of 52 per 100,000 population. Motor vehicle accidents continued to be the major cause of fatal injuries, accounting for two-fifths of all accidental deaths. Such accidents were responsible for the loss of about 37,500 lives, or about 500 more than in 1958. Data currently available indicate that the motor vehicle accident death rate per 100 million vehicle miles in 1959 was slightly less than the all-time minimum of 5.6 established a year earlier. Public accidents other than those involving motor vehicles accounted for nearly 17,000 deaths last year, or about 500 above the 1958 toll. Accidents in and about the home killed 27,000 the same number as the year before, and accidents arising out of and in the course of employment resulted in about 13,000 deaths.

Allergy Meeting in Miami Beach.—The 16th congress and graduate instructional course in allergy of the American College of Allergists will be held Feb. 28-March 4 at the Americana Hotel, Bal Harbour, Miami Beach, Fla. The instructional course, conducted Feb. 28 through March 1, will be presented under the following major titles: Primary Considerations of Some Aspects of the Field of Allergy, Clinical Applications to Present Day Knowledge in Allergy, and Progress in Allergy: The Allergist of Today and Tomorrow. Dr. Ethan Allan Brown, of London, England, present director, Asthma Research Foundation, Boston, will present "Enzymes in Allergy" March 1. Dr. James H. Putman, president, Florida Allergy Society, will open the general scientific session, March 2 followed by an address by Dr. Cecil M. Kohn, president of the American College of Allergists. Sectional meetings for pediatric allergy, technology, psychosomatic medicine, dermatologic allergy, and allergy of the nervous system are planned for March 4. Scientific exhibits are planned. For information, write the American College of Allergists, 2049 Broadway, Boulder, Colo.

White House Conference Publications Available.—The White House Conference on Children and Youth, scheduled for March 28-April 1 in Washington, D. C., has announced the availability of publications for use in the states in preparing for and following up the activities of the conference itself. The following publications are available at the prices listed, which include postage:

"The Nation's Children" (3 volumes)	$6.50 the set
"Children in a Changing World"	1.50
State Reports Digest	1.75
National Organizations Digest	1.75
Conference Proceedings	2.50
All the Above in One Order	11.30

The price offers listed above terminate as of March 26 and no assurance can be given that publications will be available at these prices thereafter. A descriptive flyer of the publications for distribution to memberships of state and national organizations is available. Requests should be addressed to Miss Helen Hamer, Publications Division, White House Conference on Children and Youth, 330 Independence Ave., S. D., Washington 25, D. C. Information is available from the same source.

College of Nutrition.—Formation of the American College of Nutrition was announced Oct. 26 by a group of New York and New Jersey specialists in nutrition, metabolic diseases, and gastroenterology. The college will not be limited to physicians in these fields but will include gerontologists, endocrinologists, surgeons, and others. Its purpose is to promote postgraduate research and education in therapeutic nutrition. The college is incorporated as a nonprofit organization subject to American Medical Association regulations. Its annual meeting will precede the A. M. A. convention in the same city each year, with the first meeting scheduled for Miami, Fla., in June. Dr. S. William Kalb, of Newark, N. J., was elected president of the new college. Dr. Kalb is chairman of the nutrition committee, Essex County Medical Society. Physicians eligible for fellowship are those whose professional activity is chiefly concerned with metabolism and nutrition and others in which nutritional or metabolic factors are important, including postoperative convalescence. Both fellowships and associate fellowships will be granted by the college. The administrative office of the organization is at 10 Oak Street, Livingston, N. J.

Award for Research in Accident Prevention.—The National Safety Council announced the Metropolitan Award for Research in Accident Prevention. One thousand dollars and an appropriate testimonial will be given for the research project in any field of accident prevention judged to be the "most significant contribution toward the reduction of accidental injuries and deaths." The award will be made "to give recognition to investigators now studying the causes of accidents to encourage research workers in the various sciences to include the problem of accident causation in their studies." Research may come from any of the various disciplines, i. e., biological, physical, or social, and can include interdisciplinary undertakings. Research may be submitted by the investigator, may be invited by the National Safety Council Committee on Research and Education, or may be nominated by anyone familiar with a research project. For information, write to Mr. John J. Flaherty, Director, Research Division, National Safety Council, 425 N. Michigan Ave., Chicago 11. This award, approved by the Executive Committee of the Board of Directors of the National Safety Council in October, 1959, will be administered by the Council under a grant from the Metropolitan Life Insurance Company.

Scholarships for Work with Crippled Persons.—For qualified persons wanting to further their training and to "better equip themselves" in working with the crippled, a new group of fellowships and scholarships are available, the National Society for Crippled Children and Adults announced. March 14 is the deadline for filing applications for 20 fellowships in counseling and job placement of the cerebral palsied and those having other physical handicaps, and April 1 is the deadline for scholarship applications for physicians, therapists, educators, and other professional persons working with children and adults having cerebral palsy. Fellowship awards are co-sponsored by the National Society and Alpha Gamma Delta, International Women's Fraternity. They cover four weeks of specialized training from June 13 to July 8 at the Institute of Physical Medicine and Rehabilitation of New York University–Bellevue Medical Center. The fellowships ($300 to be used for tuition and laboratory fees with the balance applied toward living expenses) are available to counselors and placement workers. Scholarships, co-sponsored by the national society and Alpha Chi Omega, are designed "to make more trained specialists available for serving the cerebral palsied and to supplement and increase the skill and knowledge of those already working with these persons." Courses for which scholarships are granted must have primary emphasis on cerebral palsy and participation of a member of the American Academy of Cerebral Palsy or have the prior approval of members of this academy serving as counselors to the national society. Grants are given in varying amounts up to $750, depending upon the length and scope of the course and the availability of other financial aid. Eligible to receive scholarships are physicians and other medical specialists. Applications and information can be secured from the Personnel and Reporting Service of the National Society for Crippled and Adults, 2023 W. Ogden Ave., Chicago 12.

LATIN AMERICA

Meeting on Cancer Cytology in Mexico City.—The International Conference of Cancer Cytology will be held in Mexico City May 2-11 instead of in Madrid, Spain, Dr. J. Ernest Ayre, Miami, and Dr. Locke L. MacKenzie, New York City, announced on behalf of Dr. Sanz Ibanez, of Spain, president of the conference. The announcement followed a meeting of the medical and scientific consultants of the Cancer Cytology Foundation of America, Inc., co-sponsoring the conference with the Pan American Cancer Cytology Society, the National Cancer Institute of Spain, and other medical groups. Dr. Ayre and Dr. MacKenzie, who are respectively president and U. S. national chairman of the Pan American Cancer Cytology Society, stated the conference will meet jointly with the Pan American Medical Congress. The theme of the Pan American Association Congress will be "Inter-American Good Will through Medical Science." Official support of the congress has been assured by the Minister of Health for Mexico and other government agencies and scientific organizations. The International Cancer Cytology Conference will bring together, by invitation, authorities in cancer cytology, as well as heads of WHO and UNESCO, to discuss ways and means of making cytology tests available to people of all countries. For information, write Dr. Robert E. L. Nesbitt Jr., Secretary, U. S. Office, International Conference, Union University, Albany, N. Y.

FOREIGN

Seminar Congresses in Vienna.—The American Medical Society of Vienna announced its schedule of 1960 seminar congresses held in cooperation with the medical faculty of the University of Vienna. The congresses are presented in the following specialties: dermatology and syphilology, internal medicine, neurology and psychiatry, obstetrics and gynecology, ophthalmology, orthopedic and traumatic surgery, otorhinolaryngology, pathology, pediatrics, radiology, and surgery. From 5 to 11 seminar sessions are scheduled on each specialty beginning in January, February, or April and continuing through November or December. For information on the seminar congresses, write Dr. M. Arthur Kline, executive secretary American Medical Society of Vienna, 11, Universitatsstrasse, Vienna 1, Austria.

Meeting of British and Irish Surgeons.—The Association of Surgeons of Great Britain and Ireland, 47 Lincoln's Inn Field, London, W. C. 2, under the presidency of Prof. F. A. R. Stammers, will hold its annual meeting in Birmingham on Thursday, Friday, and Saturday, April 7-9. Papers on open heart surgery will be presented following a business meeting the morning of April 7, with "Ulcerative Colitis" the theme for papers on the morning of April 9. Demonstrations and discussions on special subjects will be arranged at four hospitals the afternoon of April 8. Films, scientific exhibits, and demonstrations are planned. The annual dinner will be held at the Queen Elizabeth Hospital. For information, write Mr. Charles G. Rob, Honorary Secretary, at the above address.

EXAMINATIONS AND LICENSURE

EDUCATIONAL COUNCIL FOR FOREIGN MEDICAL GRADUATES, INC.

Educational Council for Foreign Medical Graduates: Stations around the world. March 16, 1960 and Sept. 21, 1960. Exec. Director, Dr. Dean F. Smiley, 1710 Orrington Ave., Evanston, Ill.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Part I, Various Cities, June 21-22 and Sept. 7-8. Part II, Various Cities, April 26-27. Applications must be received at least six weeks before the date of the examination. Exec. Sec., Dr. John P. Hubbard, 133 South 36th St., Philadelphia.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: *Examination.* Montgomery, June 21-23. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery.

Alaska:[*] On application in Anchorage or Fairbanks. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

Arkansas:[*] *Examination and Reciprocity.* Little Rock, June 9-10 Sec., Dr. Joe Verser, Harrisburg.

California: *Written.* Los Angeles, March 7-10; San Francisco, June 20-23; Los Angeles, Aug. 22-25 and Sacramento, Oct. 17-20. *Oral and Clinical.* Los Angeles, March 6; San Francisco, June 19; Los Angeles, Aug. 21, and Los Angeles, Nov. 29. *Oral for Reciprocity Applicants.* Los Angeles, Mar. 5; San Francisco, June 18; Los Angeles, Aug. 20 and Nov. 19. Sec., Dr. Louis E. Jones, Room 536, 1020 N Street, Sacramento.

Canal Zone: On Application. Acting Sec., Dr. B. K. Levin, Health Bureau, Balboa Heights.

Colorado:[*] *Reciprocity.* Denver, April 12. *Examination.* Denver, June 14-15. Sec., Dr. John B. Farley, 1612 Tremont Place, Denver 2.

Connecticut:[*] *Regular. Examination.* Hartford, Mar. 8-10. Sec., Dr. Stanley B. Weld, 160 St. Ronan St., New Haven. *Homeopathic. Examination.* Derby, Mar. 8. Sec., Dr. Ronald A. Davis, 38 Elizabeth St., Dover.

Delaware: *Examination and Endorsement.* Dover, June 12-14 and July 21. Sec., Dr. Joseph S. McDaniel, Professional Bldg., Dover.

District of Columbia:[*] *Reciprocity.* Washington, March 14. *Examination.* Washington, June 13-14. Deputy Director, Mr. Paul Foley, Department of Occupations and Professions, 1740 Massachusetts Ave., N.W., Washington 6.

Florida:[*] *Examination.* Miami Beach, June 19-21. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

Georgia: *Examination and Reciprocity.* Atlanta, June. Sec., Mr. Cecil L. Clifton, 224 State Capitol, Atlanta 3.

Guam: *Subject to Call.* Act Sec., Dr. F. L. Conklin, Agana.

Idaho: *Examination and Endorsement.* Boise, July 11-13. Exec. Sec., Mr. Armand L. Bird, 304 Sonna Bldg., Boise.

Indiana: *Examination.* Indianapolis, June 22-24. *Reciprocity.* Indianapolis, fourth Wednesday of each month. Ex. Sec., Miss Ruth V. Kirk, 538 K. of P. Bldg., Indianapolis.

Maine: *Examination and Reciprocity.* Brunswick, March 8-10. Sec., Dr. Daniel F. Hanley, Box 637, Brunswick.

Maryland: *Examination.* Baltimore, June 15-18. Sec., Dr. Frank K. Morris, 1215 Cathedral St., Baltimore 1.

Michigan:[*] *Examination.* Ann Arbor and Detroit, June 6-8. Sec., Dr. E. C. Swanson, 118 Stevens T Mason Bldg., Lansing.

Mississippi: *Examination.* Jackson, June. Sec., Dr. A. L. Gray, Old Capitol, Jackson 13.

Montana: *Examination and Reciprocity.* Helena, April 5. Sec., Dr. Thomas L. Hawkins, 555 Fuller Ave., Helena.

Nebraska:[*] *Examination.* Omaha, June 13-15, 1960. Dir., Bureau of Examining Boards, Room 1009, State Capitol Bldg., Lincoln 9.

Nevada:[*] *Examination and Reciprocity and Endorsement.* Reno, March 8. Sec., Dr. G. H. Ross, 112 No. Curry St., Carson City.

New Hampshire: *Examination.* Concord. March 9-12. Sec., Dr. Edward W. Colby, 61 South Spring St., Concord.

New Mexico:[*] *Examination and Reciprocity.* Santa Fe, May 16-17. Sec., Dr. R. C. Derbyshire, 227 East Palace Ave., Santa Fe.

New York: *Examination.* Albany, Buffalo, New York City, Rochester and Syracuse, June 28-July 1. Sec., Dr. Stiles D. Ezell, 23 S. Pearl Street, Albany.

North Carolina: *Endorsement.* Raleigh, May 9. *Examination and Endorsement.* Raleigh, June 20-23. Sec., Dr. Joseph J. Combs, 716 Professional Bldg., Raleigh.

North Dakota: *Examination and Reciprocity.* Grand Forks, July 6-9. Sec., Dr. C. J. Glaspel, Grafton.

Ohio: *Reciprocity.* Columbus, April 5 and June 17. *Examination.* Columbus, June 16-18. Sec., Dr. H. M. Platter, 21 West Broad St., Columbus 15.

Oklahoma:[*] *Examination and Endorsement.* Oklahoma City, May 31-June 1. Sec., Dr. E. F. Lester, 813 Braniff Bldg., Oklahoma City.

Oregon:[*] *Reciprocity and Endorsement.* Portland, April 14-16. *Examination.* Portland, July. Exec. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland.

Pennsylvania: *Endorsement.* Harrisburg, March 3. *Examination.* Philadelphia and Pittsburgh, July 5-7. Sec., Mrs. Margaret G. Steiner, Box 911, Harrisburg.

Puerto Rico: *Examination.* San Juan, March 1-5. Sec., Dr. Herminio Mendez Herrera, Box 9156 Santurce.

Rhode Island:[*] *Endorsement.* Providence, March 24. *Examination.* Providence, April 7-8. Administrator of Professional Regulations, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

Tennessee:[*] *Examination.* Memphis, March 23-24. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis 3.

Texas:[*] *Examination and Reciprocity.* Fort Worth, June 20-22. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

Utah: *Examination.* Salt Lake City, July 6-8. Director, Mr. Frank E. Lees, 324 State Office Bldg., Salt Lake City 1.

Virginia: *Examination and Reciprocity.* Richmond, June 13-17. Address: Board of Medical Examiners, 631 First St. S.W., Roanoke.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arizona: *Examination.* Tucson, March 18. *Endorsement.* Tucson, March 15. Sec., Mr. Herman E. Bateman, University of Arizona, Tucson.

Arkansas: *Examination.* Little Rock, April 21-22. Sec., Dr. A. W. Ford, Department of Education, Education Bldg., Little Rock.

Colorado: *Examination and Reciprocity.* Denver, March 2-3. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 18.

District of Columbia: *Examination.* Washington, May 23-24. Deputy Director, Mr. Paul Foley, Department of Occupations and Professions, 1740 Massachusetts Ave., Washington 6.

Florida: *Examination.* Miami, June 4. Sec., Mr. M. W. Emmel, Box 340, Gainesville.

Iowa: *Examination and Reciprocity.* Des Moines, April 12. Sec., Mr. Elmer W. Hertel, Wartburg College, Waverly.

Kansas: *Examination.* Kansas City, June 10-12. Sec., Dr. Leon C. Heckert, Kansas State College, Pittsburg.

Minnesota: *Examination.* Minneapolis, April 5-6. Sec., Dr. Raymond N. Bieter, 165 Millard Hall, University of Minnesota, Minneapolis.

Nebraska: *Examination.* Omaha, May 3-4. Sec., Mr. R. K. Kirkman, Room 1009, State Capitol Bldg., Lincoln 9.

Nevada: *Examination.* Reno, March. Sec., Dr. Kenneth C. Kemp, Box 9355, University of Nevada, Reno.

Oklahoma: *Examination.* Oklahoma City, April 15-16. Exec. Sec., Mrs. E. L. Haidek, 813 Braniff Bldg., Oklahoma City.

Oregon: *Examination.* Portland, March 5. Sec., Dr. Earl M. Pallett, State Board of Higher Education, Box 5175, Eugene.

Tennessee: *Examination.* Memphis and Nashville, March 23-24. Sec., Dr. O. W. Hyman, 62 S. Dunlap St., Memphis.

Texas: *Examination.* Austin, Houston and Galveston, June 20-22. Sec., Dr. Cornelia M. Smith, State Office Bldg., 201 East 14th St., Austin.

Washington: *Examination.* Seattle, July 13-14. Administrator, Mr. Thomas A. Carter, Department of Licenses, Capitol Bldg., Olympia.

Wisconsin: *Examination.* Madison, April 9. Milwaukee, June 4. Sec., Dr. W. H. Barber, 621 Ransom St., Ripon.

---

[*] Basic Science Certificate required.

GOVERNMENT SERVICES

AIR FORCE

Medical Service School.—The Gunter Branch of the School of Aviation Medicine was redesignated the Medical Service School. It was originally established in 1950 to meet the training requirements of medical personnel during the Korean conflict. The present mission of the school is to conduct all military medical training for officers and airmen except that which is directly related to aviation medicine; to provide the necessary administrative support and supervision for all personnel assigned or attached to the school; and to organize, equip, and train, on a continuing basis, a medical disaster assistance team. Thirty-six different courses are offered, 12 for officers, 10 for advanced or supervisory technicians, and 14 for apprentice-specialist airmen.

NAVY

Reserve Training Course.—A two-week active duty course in military medical training, previously scheduled to convene on March 7, will convene March 14, at the Naval Medical School, Bethesda, Md. The first week will be devoted to medical aspects of special weapons and radioactive isotopes, with particular reference to casualties from atomic explosions. The second week will be devoted to professional topics of concern to military medicine, including discussions on reserve medical programs of the Armed Forces. Naval Reserve Medical Department officers are eligible for this course. Quotas have been authorized to commandants of the First, Third, Fourth, Fifth, Sixth, Eighth, and Ninth Naval Districts. Interested, eligible officers should submit a request for this training to their respective naval districts. Those who are ready reservists are eligible for active duty training with pay, and those who are standby reservists are eligible to participate in this training without pay.

PUBLIC HEALTH SERVICE

Assistant Surgeon General.—Dr. Arnold B. Kurlander, formerly deputy chief of the bureau of medical services, was named the assistant surgeon general of the Public Health Service. As assistant surgeon he is third in command. His specific area of responsibility will be to provide immediate staff assistance to the surgeon general on current program matters, to facilitate communications between the four bureaus of the service and the surgeon general's office, and to expedite the handling of program aspects of operating problems.

Water Pollution.—The water pollution control advisory board to the surgeon general met in January and recommended that (1) the Secretary of Health, Education, and Welfare support approval of a bill to increase grants for the construction of water treatment works, (2) the budget contain a separate item for water pollution control activities, (3) all federal and other public installations having waste disposal problems set an example to the rest of the country by better cooperation with state water pollution control agencies and the Public Health Service in installing needed waste treatment facilities, (4) the provisions of the Federal Water Pollution Control Act be strengthened to provide a more equitable mechanism for preserving and improving the quality of water supplies and that it be amended so that sources of pollution will not be exempt from the provisions of the act merely because of fortuitous geographical location, (5) additional cooperative state-Public Health Service basic data stations be established to provide information on the quality of our nation's water so as to enable states, localities, industries, and the federal government to protect public health and conserve water sources for public water supplies, propagation of aquatic life and wildlife, recreational purposes, and agricultural, industrial, and other legitimate uses, and (6) the enforcement provisions of the Federal Water Pollution Control Act be expanded to cover discharges from federal installations.

DEPARTMENT OF JUSTICE

Personal.—Dr. D. J. Lacovara was transferred from the Federal Correctional Institution, Ashland, Ky., to the Federal Correctional Institution, Lompoc, Calif., where he is chief medical officer and chief of the psychiatric service. This institution is a much-needed adjunct for those cases requiring 60 to 90 days of observation and study, pursuant to provisions of statutes designed to make available to federal judges more complete studies prior to imposition of final sentencing, with particular stress on the personality and mental status of the prisoner.

NATIONAL SCIENCE FOUNDATION

New Grants Brochure.—The January, 1960, revision of the National Science Foundation brochure, "Grants for Scientific Research," contains instructions for submission of proposals and information on administration of Foundation grants. Its terms become a part of all Foundation research grants. This revision contains new explanatory material on Foundation grant policies and some revisions of earlier instructions. Copies can be obtained from the National Science Foundation, Washington 25, D. C.

DEATHS

Abell, Charles Eckley Ⓜ Canton, Ohio; University Medical College of Kansas City, Mo., 1903; past-secretary of the Stark County Medical Society; died Nov. 7, aged 87.

Powers, Harris Earle Ⓜ Manchester, N. H.; Tufts College Medical School, Boston, 1916; fellow of the American College of Surgeons; served on the staffs of the Elliott, Notre Dame de Lourdes, and Sacred Heart hospitals; died Nov. 4, aged 67.

Reichard, Orill Ⓜ Flint, Mich.; University and Bellevue Hospital Medical College, New York City, 1905; associated with the McLaren and St. Joseph hospitals, and the Hurley Hospital, where he died Nov. 10, aged 81.

Reichman, John Joseph, Hannibal, Mo.; St. Louis University School of Medicine, 1929; on the staffs of the Levering and St. Elizabeth hospitals; died Nov. 6, aged 53.

Romonek, Philip L. Ⓜ Beverly Hills, Calif.; Loyola University School of Medicine, Chicago, 1921; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; on the faculty of the University of California at Los Angeles School of Medicine; at one time on the faculty of the University of Nebraska College of Medicine in Omaha, where he was on the staff of the Lutheran Hospital; served on the staffs of St. John's Hospital in Santa Monica and Cedars of Lebanon Hospital in Los Angeles; died in the Mount Sinai Hospital in Los Angeles, Nov. 9, aged 64.

Rudderow, Edward Douglas Ⓜ New York City; New York Homeopathic Medical College and Hospital, New York City, 1895; served on the faculty of the New York Medical College and Hospital for Women and his *alma mater*; veteran of World War I; on the welfare board of the Metropolitan Hospital; on the staff of the Flower and Fifth Avenue hospitals; died in Stamford, Conn., Nov. 15, aged 87.

Rusmisell, James Adam Ⓜ Buckhannon, W. Va.; Maryland Medical College, Baltimore, 1904; veteran of World War I; on the staff of the Elizabeth Coplin Leonard Hospital, where he died Nov. 4, aged 80.

Rutherford, Samuel C. Ⓜ Tulsa, Okla.; University of Arkansas School of Medicine, Little Rock, 1901; died in Pryor Nov. 13, aged 90.

Santo, Ralph Verrei, Abington, Pa.; Temple University School of Medicine, Philadelphia, 1945; interned at the Newark City Hospital and St. James Hospital in Newark, N. J.; veteran of World War II; died Nov. 5, aged 40.

Saphir, Joseph Frederick Ⓜ Peekskill, N. Y.; Columbia University College of Physicians and Surgeons, New York City, 1902; member of the American Proctologic Society; served as an honorary surgeon of the New York City Police Department; formerly chief of proctology at Manhattan State Hospital, New York City; died Nov. 26, aged 78.

Saxe, Le Roy Hallowell, Shippensburg, Pa.; Jefferson Medical College of Philadelphia, 1905; past-president of the Franklin County Medical Society; served on the staff of the Carlisle (Pa.) Hospital; died Oct. 21, aged 80.

Schaiberger, Elmer George Ⓜ Birch Run, Mich.; University of Michigan Medical School, Ann Arbor, 1928; interned at St. Mary's Hospital in Grand Rapids; formerly practiced in Saginaw, where he was county coroner; died in St. Joseph's Retreat Hospital, Dearborn, Oct. 30, aged 59.

Schott, Theodore Joseph Ⓜ Yakima, Wash.; St. Louis University School of Medicine, 1928; on the staff of St. Elizabeth Hospital; died in the University Hospital, Seattle, Oct. 31, aged 55.

Schwartz, Frederick Leonhardt Ⓜ San Diego, Calif.; University of Buffalo School of Medicine, 1917; fellow of the American College of Surgeons and the International College of Surgeons; formerly served in the regular U. S. Navy; associated with the Mercy Hospital; on the staff of the Scripps Memorial Hospital in La Jolla; died Nov. 13, aged 62.

Schwarz, Rudolph Ⓜ Phoenix, Ariz.; Medizinische Fakultät der Universität, Vienna, Austria, 1921; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; served as senior clinical psychiatrist at Sing Sing Prison; died Nov. 1, aged 64.

Sealover, William Frederic, Zanesville, Ohio; Starling Medical College, Columbus, 1900; veteran of World War I; on the staffs of the Bethesda and Good Samaritan hospitals; died Nov. 9, aged 81.

Sennott, John Ralph Ⓜ Cambridge, Mass.; Harvard Medical School, Boston, 1902; served on the staffs of the Cambridge City Hospital and the Holy Ghost Hospital; died Nov. 17, aged 81.

Smith, John Wesley, Gassaway, W. Va.; University of the South Medical Department, Sewanee, Tenn., 1898; died Nov. 10, aged 86.

Soanes, Jabez George N. Ⓜ Kansas City, Kan.; Howard University College of Medicine, Washington, D. C., 1901; for many years police surgeon; died in the Douglass Hospital Nov. 5, aged 85.

Spector, Isaac, St. Louis; Baltimore Medical College, 1905; died in the Jewish Hospital Oct. 17, aged 86.

Stapleton, Willard Pierce, Gardner, Mass.; Bennett Medical College, Chicago, 1915; veteran of World War I; served on the staff of the Henry Heywood Memorial Hospital; died Nov. 4, aged 67.

Stickney, Whitman Gibson, Beverly, Mass.; Tufts College Medical School, Boston, 1901; for many years medical examiner in the Seventh Essex District; served as school physician; died Nov. 17, aged 90.

Stowell, Fred Austin Ⓜ Newburyport, Mass.; Pulte Medical College, Homeopathic, Cincinnati, 1902; died Oct. 26, aged 92.

Swallum, James Alva, Storm Lake, Iowa; the Hahnemann Medical College and Hospital, Chicago, 1901; died in the Sioux Valley Hospital, Cherokee, Sept. 11, aged 85.

Swan, Alfred Hjalmar Ⓜ Pearblossom, Calif.; Rush Medical College, Chicago, 1921; for many years practiced in Shanghai, China; died Nov. 3, aged 75.

Swanson, John Theodore Ⓜ Independence, Kan.; University of Kansas School of Medicine, Kansas City, 1908; specialist certified by the American Board of Radiology; member of the Radiological Society of North America and the American College of Radiology; veteran of World War I; served on the staff of the Mercy Hospital; died Nov. 16, aged 80.

Tabor, Sidney Johnston Ⓜ Portsmouth, Va.; Vanderbilt University College of Medicine, Nashville, Tenn., 1892; died Nov. 9, aged 92.

Taylor, Zella Eileen, Winchester, Mass.; Boston University School of Medicine, 1933; interned at the Mary Hitchcock Memorial Hospital in Hanover, N. H., and the Hospital for Women, Baltimore; certified by the National Board of Medical Examiners; died Nov. 1, aged 53.

Thomas, Charles Anslem Ⓜ Tucson, Ariz.; Medical Department of Tulane University of Louisiana, New Orleans, 1905; formerly associated with the Indian Service; fellow of the American College of Surgeons; past-president of the Southwestern Medical Association, Pima County Medical Society, and the Arizona Medical Association; veteran of World War I; past-president and honorary member of the staff of St. Mary's Hospital and was a member of the staff of the Tucson Medical Center; died Nov. 5, aged 82.

Tolleson, George W., Amity, Ark.; University of Arkansas School of Medicine, Little Rock, 1898; one of the founders of the Pike County Bank, Murfreesboro; president of the Bank of Amity; died in Hope Nov. 12, aged 89.

Townsend, Willis Merrick Ⓜ Melrose, Mass.; Boston University School of Medicine, 1893; for many years associated with the Melrose Hospital; died Nov. 11, aged 89.

Trescher, John Henry Ⓜ Baltimore; Cornell University Medical College, New York City, 1924; member of the American Academy of Allergy; associated with the Johns Hopkins Hospital, Union Memorial Hospital, Hospital for the Women of Maryland, and Sinai Hospital; died Nov. 15, aged 60.

Trimble, Volantus G., Somerset, Ky.; University of Louisville Medical Department, 1909; veteran of the Spanish-American War; died in the Somerset City Hospital Oct. 9, aged 82.

Turner, Vernon C. Ⓜ Evanston, Ill.; born in Banks, Ore., Sept. 19, 1907; University of Oregon Medical School, Portland, 1936; specialist certified by the American Board of Orthopaedic Surgery; member of the Clinical Orthopaedic Society, American Academy of Orthopaedic Surgery, and of the American Rheumatism Association; fellow of the International College of Surgeons and the American College of Surgeons; past-president of the Chicago Orthopaedic Society; member of the medical advisory committee of the Arthritis Foundation; served as associate professor of orthopaedic surgery, Northwestern University Medical School; for many years on the staff of the Evanston Hospital; consultant, Swedish Covenant Hospital; died Nov. 21, aged 52.

Tylbor, Rubin, New York City; Uniwersytet Jozefa Pilsudskiego, Warszawa, Poland, 1926; served a residency at the Willard Parker Hospital; died Nov. 8, aged 63.

Vance, James Ⓜ El Paso, Texas; Hospital College of Medicine, Louisville, Ky., 1899; past-president of the El Paso County Medical Association and the Southwestern Medical and Surgical Association; while in Louisville, Ky., served as president of the Louisville Surgical Society; served on the faculty of the University of Louisville (Ky.) School of Medicine; veteran of World War I; fellow of the American College of Surgeons; associated with Hotel Dieu, Sisters Hospital, Southwestern General and Providence Memorial hospitals; died Dec. 2, aged 84.

Van Voorhis, Clyde Randolph, Prairie City, Iowa; Drake University College of Medicine, Des Moines, 1904; veteran of World War I; for many years on the staff of the Iowa Lutheran Hospital in Des Moines; died in the Veterans Administration Hospital, Des Moines, Nov. 10, aged 82.

Vian, George Martin Vaznaian Ⓜ Woonsocket, R. I.; Georgetown University School of Medicine, Washington, D. C., 1939; veteran of World War II; served on the staffs of St. Joseph's Hospital in Providence, and Woonsocket Hospital; died Nov. 8, aged 45.

Walsh, Arthur F. Ⓜ Grafton, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1899; died in the Mercy Hospital, Pittsburgh, Nov. 3, aged 84.

Waugh, Richey Laughlin Ⓜ Medical Director, U. S. Public Health Service, retired, Arlington, Mass.; University of Minnesota Medical School, Minneapolis, 1915; member of the American Academy of

Orthopaedic Surgeons and the American Association for the Surgery of Trauma; fellow of the American College of Surgeons; in 1947 awarded the Founders Medal of the Association of Military Surgeons of the United States; died Nov. 24, aged 71.

Webster, Daniel Jefferson Ⓜ Ironton, Ohio; Miami Medical College, Cincinnati, 1893; past-president of the Lawrence County Medical Society; died Nov. 21, aged 92.

Weil, Frederic Samuel Ⓜ New York City; Universität Basel Medizinische Fakultät, Switzerland, 1927; specialist certified by the American Board of Psychiatry and Neurology; member of the American Academy of Neurology and the American Psychiatric Association; faculty member of the New York Psychoanalytic Institute; from 1942 to 1947 adjunct psychiatrist at Mount Sinai Hospital; died in the Doctors Hospital Nov. 6, aged 59.

West, Edward McMichael Ⓜ Atlanta, Ga.; Medical College of Georgia, Augusta, 1946; on the staff of the Grady Hospital; died Nov. 13, aged 38.

Wharton, May Cravath Ⓜ Pleasant Hill, Tenn.; University of Michigan Homeopathic Medical School, Ann Arbor, 1903; founded the Uplands Cumberland Sanatorium; died Nov. 19, aged 86.

White, Hal Hugh Ⓜ Paris, Texas; University of Louisville (Ky.) Medical Department, 1901; fellow of the American College of Surgeons; associated with the Sanitorium of Paris, where he died Nov. 21, aged 82.

Whitmer, Ralph Glenn Ⓜ Des Moines, Iowa; Rush Medical College, Chicago, 1927; member of the American Academy of General Practice; veteran of World Wars I and II; formerly on the staffs of the West Suburban Hospital in Oak Park, Ill., and the Community General Hospital in Sterling, Ill.; associated with the Veterans Administration Hospital; died Nov. 12, aged 70.

Wiesbader, Hans Wilhelm Ⓜ New York City; Universität Heidelberg Medizinische Fakultät, Baden, Germany, 1923; on the staff of the Bellevue Hospital; died in the Montefiore Hospital Nov. 4, aged 59.

Williams, Arthur Frederick Ⓜ Fort Morgan, Colo.; Denver and Gross College of Medicine, 1903; member of the Radiological Society of North America; died Nov. 21, aged 78.

Williams, Earle Ⓜ Brooklyn, Ill.; Jenner Medical College, Chicago, 1907; member of the American Academy of General Practice; past-president of the board of education; member of the staffs of St. Mary's and Christian Welfare hospitals in East St. Louis, St. Elizabeth's Hospital of Granite City, St. Mary's Infirmary and People's Hospital in St. Louis; died Nov. 5, aged 74.

Williams, Hiram Griffith Ⓜ Prentiss, Miss.; Atlanta College of Physicians and Surgeons, 1902; died in the Jefferson Davis County Hospital Nov. 12, aged 84.

Williams, Robert Vincent Ⓜ Flushing, N. Y.; Fordham University School of Medicine, 1913; veteran of World War I; for many years police surgeon; associated with the Midtown Hospital, New York City, and Flushing Hospital, where he was past-president of the medical board and where he died Nov. 18, aged 73.

Willis, Jack Edward Ⓜ Mill Valley, Calif.; Stanford University School of Medicine, San Francisco, 1945; interned at the Stanford University Hospitals, San Francisco, where he served a residency; formerly a resident at the San Francisco Hospital; resigned from the regular U. S. Army June 17, 1952; associated with the Marin General and San Rafael General hospitals; died in the California Medical Facility, Department of Corrections, Vacaville, Nov. 24, aged 41.

Wiseley, Allen Newton, South Laguna, Calif.; Rush Medical College, Chicago, 1913; formerly practiced in Lima, Ohio, where he was past-president of the Allen County Academy of Medicine, and member of the city board of education; served on the staff of the Lima Memorial and St. Rita's hospitals in Lima, Ohio; died Nov. 2, aged 76.

Workman, Meyer, New York City; University and Bellevue Hospital Medical College, New York City, 1918; died in the New York Hospital Oct. 29, aged 63.

Wood, Gordon Lee Ⓜ Andalusia, Ala.; University of Alabama School of Medicine, Mobile, 1910; affiliated with the Covington Memorial Hospital; died in St. Margaret's Hospital, Montgomery, Oct. 28, aged 76.

Worthington, Arthur Morton Ⓜ Dedham, Mass.; Harvard Medical School, Boston, 1896; served on the faculty of his alma mater; for many years bacteriologist for the board of health; past-president of the Dedham Historical Society; veteran of World War I; died Nov. 11, aged 89.

Wright, James J. C., Rockmart, Ga.; Hospital Medical College, Eclectic, Atlanta, 1909; died Oct. 27, aged 72.

Wyser, Dorean David, Ossining, N. Y.; Medizinische Fakultät der Universität, Wien, Austria, 1920; specialist certified by the American Board of Radiology; member of the American College of Radiology; served on the staffs of the Peekskill (N. Y.) Hospital and the Ossining Hospital; died Nov. 6, aged 67.

FOREIGN LETTERS

GERMANY

Problems of Blood Transfusion.—W. Lutzeyer (*Arch. klin. Chir.* 290:576, 1959) stated that the number of blood transfusions given has increased tenfold in the last 10 years. Although cross-matching should be done on every patient, subtyping of group A can be ignored since the purpose of cross-matching is to discover irregular cold antibodies. From a serologic point of view there are no donors whose blood can be used for any patient. The group O donor possesses a high titer of agglutinins and isohemolysins in 4 or 5% of cases. The use of group O, Rh negative, blood is justified only under unusual circumstances. A questionnaire sent to 80 blood banks revealed that cross-matching was usually performed in only one direction. Of those blood banks 66 denied that there was an increased incidence of transfusion reactions in patients with group A blood.

To avoid pyrogenic reactions stored blood should not be given before the 3rd day or later than the 14th day after donation. A definite decrease in the incidence of reactions to transfusions since the introduction of stored blood was reported by 72 banks. The incidence of pyrogenic reactions to stored blood was 0.3 to 2.5%. A further significant reduction in the incidence of these reactions followed the introduction of the disposable transfusion kits. The addition of drugs to stored blood to prevent pyrogenic reactions was not recommended. About 4% of stored blood was bacterially contaminated, chiefly with coliform organisms. Sterility tests increase the danger of bacterial contamination. According to the replies 56 of the banks had seen no bacteriotoxic reactions to transfusion. Stored blood which is no longer vacuum-sealed, or which has undergone obvious hemolysis, should always be suspected of contamination. The addition of 0.2 Gm. of leukomycin to each bottle reduced the incidence of reactions by a further 33% without causing allergic symptoms. The most frequent cause of accidents was air embolism resulting from transfusion under pressure.

Transfusion with fresh blood may cause a delay in clotting. Stored blood coagulates best about five days after it has been taken. In patients with acquired or congenital anomalies of coagulation (e. g., hemophilia), however, the tendency to increase bleeding is aggravated by transfusion with stored blood. The tendency of some surgical patients to excessive bleeding may be due to (1) faulty transfusion technique, masked by the anesthetic, (2) pyrogenic reactions, (3) extensive operations on the lung, (4) fall in blood pressure during operation, (5) hypothermia, or (6) preoperatively given anticoagulants or antibiotics.

Mucoviscidosis.—E. Koch of Giessen (*Deutsche med. Wchnschr.* 84:1773, 1959) stated that hereditary mucoviscidosis occurs even more frequently in adults than in infants and children. The cause of the condition is a disturbance of the function of many of the exocrine glands, which take the form of the secretion of an abnormally viscid mucus. The diagnosis is based on excretory pancreatic insufficiency (due to cystic fibrosis of the pancreas), bronchiectasis, pulmonary emphysema, and a constantly raised level of sodium and chloride in the sweat combined with mineral loss and low blood pressure. Investigation of 41 families in which mucoviscidosis was found showed the condition to be inherited as an autosomal dominant gene.

Of 41 adults with hereditary mucoviscidosis 17 were found to have florid or healed peptic ulcers. In 12 of the families investigated 19 relatives were also found to have peptic ulcer and mucoviscidosis. A high incidence of peptic ulcers was found in the families of patients in this series who had no evidence of ulcer. Two patients died as a result of the pulmonary emphysema and cor pulmonale. Postmortem examination confirmed the clinically recognized combination of mucoviscidosis and duodenal ulcer. This is the first time that mucoviscidosis has been recognized clinically and pathologically in an adult. Of 43 selected ulcer patients all the cardinal symptoms of mucoviscidosis were well developed in 4, and many others showed one or more of these symptoms. Raised electrolyte concentrations in the sweat were found in 9, early pulmonary emphysema in 9, and a marked reduction or absence of one or more of the pancreatic enzymes in the duodenal juice in 25. Half of the patients with peptic ulcer showed none of the cardinal symptoms of mucoviscidosis.

In order to test the specificity of the cardinal symptoms 35 patients with cholangitis or hepatitis and a varying degree of pancreatic involvement were investigated. Of these, 12 showed a uniform and marked decrease in all the enzymes of the duodenal juice, i. e., not the dissociated decrease characteristic of mucoviscidosis. Electrolytic disturbances, on the other hand, were always absent. In-

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

vestigation of 32 healthy subjects and 88 patients with various conditions showed normal electrolyte concentrations in the sweat and normal pancreatic enzyme activity.

The incidence of peptic ulcer and mucoviscidosis in combination was at least 10 times as common as it would be in a random distribution. This was probably due to the structural changes in the gastric and duodenal mucosa. According to the pathologists the histological changes in the gastrointestinal mucosa in mucoviscidosis are as great as those in the pancreas and the bronchial tree. Apart from these inherent anomalies, trauma or irritation play a role. The fact that certain families show an increased incidence of peptic ulcers is adequately explained by these findings.

Treatment of Psychoses.—Dickhaut and Pyrkosch of Hamburg (*Nervenarzt* 29:367-370, 1958) said that successful results of treatment with promazine were reported in 850 patients with acute psychoses. In 85% of the patients the symptoms were controlled immediately. In one of the closed wards of the Hamburg psychiatric clinic a further 85 patients were treated with promazine. Over a total period of three months 100 to 200 mg. of promazine was given three or four times daily to each patient for 2 to 32 days at a time. The patients treated in this way had alcoholic delirium, postrheumatic psychoses, arteriosclerotic agitation, and endogenous psychoses. Promazine was as effective as chlorpromazine. The toxicity of promazine was less but the duration of its effect was shorter. Like chlorpromazine it had a purely symptomatic effect. No undesirable side-effects were observed. Intravenous injection produced an immediate tranquilizing effect. Intravenously given doses of hypnotics, analgesics, and narcotics had a stronger effect than oral doses. Promazine is a serviceable drug which acts at a subcortical level to depress psychomotor excitement of various origins.

Antibiotic-Resistant Staphylococci.—H. G. Fischer (*Deutsche med. Wchnschr.* 84:257-258, 1959) said that not all hemolytic staphylococci are resistant to antibiotics. The following resistances were found for staphylococci: 57% were resistant to penicillin, 45% to streptomycin, 13% to tetracycline, and 2% to chloramphenicol. One must, however, take into account the source of the material sent in for culture. For instance, 57% of all strains isolated in the Kiel University clinic were resistant to penicillin, whereas in general practice only 25% were thus resistant. In the surgical outpatient department of the university the rate went as high as 73%. If it be remembered, too, that practitioners usually take cultures for sensitivity tests only if treatment with an antibiotic has failed, then it must be assumed that the true resistance rate is even lower than 25%.

Iron and Copper Metabolism and Malignancy.—E. Kautzsch (*Medizinische* no. 40, p. 1851, 1959) stated that malignant neoplasms are associated with a characteristic alteration in serum iron and serum copper levels. Epithelial and mesenchymal new growths behave similarly with a moderate reduction in the level of the transport iron and an increase in the level of serum copper. The findings are similar to those in persons with acute and chronic infections (type 2). Hemorrhage associated with neoplastic disease gives rise to a particularly severe fall in the serum iron level (a combination of functional types 2 and 4). Neoplasms of the hemopoietic system (leukemia, multiple myeloma, lymphogranulomatosis, etc.) behave in principle similarly to other neoplasms except that increased hemolysis coupled with a decreased rate of erythropoiesis tends to have a dominant effect on the clearance of iron from the serum. In such cases raised serum copper levels are found in combination with markedly raised levels of serum transport iron (a combination of functional types 2 and 3).

It appears from investigations of 200 patients that no particular degree of alteration in the level of the serum transport iron can be ascribed to any particular type or site of neoplasia. In contrast, markedly raised serum copper levels (over 200 mcg. per 100 ml.) always suggest prostatic carcinoma or Hodgkin's disease. In the treatment of neoplastic disease by cytostatic drugs or surgery the serum iron and copper levels are a valuable guide to the success of the treatment and an indication of metastasis formation.

Dishabituation to Nicotine.—Jost and Jochum (*Med. Klin.* 54:1049, 1959) said that nicotine is contraindicated in patients with myocardial insufficiency, coronary thrombosis, thromboangiitis obliterans, arteriosclerotic disturbances of circulation, and angina pectoris. The so-called nicotine-free tobaccos still contain 0.1 to 0.2% of nicotine. Filter tips generally eliminate the noncarcinogenic hydrophilic substances but not the fat-soluble carcinogenic substances and nicotine. Thus the only way to avoid nicotine is to give up smoking.

Rinsing the mouth with silver nitrate, sucking tablets, or chewing gum to spoil the taste of cigarettes, and using various ethereal oils and quinine compounds has, for the most part, failed to have any lasting effect. Patients have, however, been enabled to give up smoking after treatment with lobeline, which has an antagonistic effect on nicotine. The patients are given 10 mg. of lobeline in a glass of water, and this is drunk a mouthful at a time throughout the day. Treatment lasts 10 to 14 days. Even better results are achieved with resident patients in a "dishabituation collective" where psychotherapy can also be used. In such circumstances patients are given 20 mg. of lobeline intramuscularly one to three times a day. Generally the first symptoms are apparent within 12 to 24 hours. They take the form of nausea, vomiting, fall in skin temperature, fall in blood pressure, sweating, giddiness, headache, and loss of taste for cigarettes. This symptom-complex occurs only when a cigarette is smoked and seldom gives rise to collapse. If the treatment is not successful within 14 days the patient should be given a rest, since the effects can be produced again only after an interval if no positive results have been obtained in the first instance.

Renal Tumors in Childhood.—P. Kolle of Munich (*Deutsche med. Wchnschr.* 84:1256-1260, 1959) stated that in 1930 tumors were not among the 10 commonest causes of death in childhood. Today, however, they are the second commonest cause. Foremost among such tumors are the embryonal mixed renal tumors, or Wilms's tumors, which comprise 20% of all tumors of childhood. These embryonal tumors also occur in adults and may grow to an extraordinary size. In half the patients metastases are already demonstrable by the time the diagnosis is made, and these are generally situated in lung and liver as well as in the regional and para-aortic lymph nodes. Diagnosis is difficult, since the tumor itself is often the only symptom. Hematuria occurs in only 10 to 20% of cases and bears an unfavorable prognosis. Signs of ileus and generalized systemic symptoms indicate the presence of metastases. In the differential diagnosis neuroblastoma, hydronephrosis, and retroperitoneal sarcoma must be ruled out. The diagnosis can be confirmed by gentle palpation and by pyelography. Renal biopsy is contraindicated because of the danger of dissemination.

The treatment of choice seems to be nephrectomy followed immediately by radiotherapy with 4,000 to 5,000 r and possibly preceded by irradiation to reduce the size of the tumor before operation. Recurrences occur generally within the first year so that the two-year cure rate is essentially equivalent to the five-year cure rate in adults. If the operation is performed as soon as possible the chances of cure are about 20%, and they increase with increasing age in childhood. The prognosis is most favorable if the diagnosis is made in the first half-year of life and treatment is begun at once.

Vesical Carcinoma.—Sievers and Marzoli of Kiel University (*Med. Klin.* 54:366-368, 1959) used DG 428 in the treatment of 27 patients who had carcinoma of the bladder. DG 428 is a synthetic thymine derivative and antimetabolite which interferes with glycolysis in the tumor cells, thus inhibiting their growth. Inhibition of tumor growth, confirmed by cystoscopy, was accompanied by a marked decrease in the severity of urinary symptoms and tenesmus. Blood and liver function were checked regularly as a safety measure. No leukopenic changes or liver damage were observed. Seven of the 27 patients died of uremia and metastases. Only 3 of the remaining 20 had bladder symptoms when they were last examined, and in these 3 the treatment had no effect on the growth of the tumor. Seventeen patients were symptom-free and were able to do part-time work. On the average they were able to go five hours without passing urine. The average capacity of the bladder was 80 cc. four weeks after the start of treatment and was 250 cc. in all patients when they were last seen. Eight patients have been observed for more than a year and two for more than two years. A marked regression of the tumor has been confirmed in 6 of the 17 patients by cystoscopy and radiography. In the others only an inhibition of the growth occurred.

Sulfobromophthalein Clearance.—Examination of 51 patients with proved chronic liver disease led A. Krautwald and co-workers of Berlin (*München. med. Wchnschr.* 101:2057, 1959) to conclude that the sulfobromophthalein clearance test is prolonged in patients with (1) chronic hepatitis, (2) chronic hepatitis passing into cirrhosis, or (3) cirrhosis. The extent of the prolongation paralleled the severity of the liver damage. Electrophoretically, the decrease in albumin levels and the increase in γ-globulin levels were significant only in the third group. While the second group showed a pronounced tendency toward the above-mentioned changes in albumin and γ-globulin levels, electrophoresis could not be used by itself diagnostically in the patients of group 1. Determination of prothrombin time did not show a definite lowering in any of the patients in this series. In the early stages of general liver damage the sulfobromphthalein test gave the most reliable results of all the procedures used.

HUNGARY

Bronchial Asthma.—K. Hajós and M. Hajós (*Acta allergol.* 14:87-99, 1959) reported that in a group of 1,000 asthmatic patients the environment influenced the course of the disease and therapeutic results. Family conflicts affected adversely 163 patients of the series, economic changes 241, and the intensification of psychic stress during the war 143. Apart from a number of asthmatic attacks evidently caused by occupation, the patient's profession per se was responsible for deterioration in 124 patients. Change of profession (physical to intellectual and vice versa) had no significant influence. The welfare of asthmatic persons did not depend entirely on organized therapy but on consecutive lesions and secondary diseases as well. Emphysema was seen in 748, chronic bronchitis in 392, and signs of right heart preponderance in 221 patients. Genuine asthmatic death occurred in 158. Therapeutic success, working capacity, and duration of the disease seemed to be influenced by preventable stresses.

INDIA

Family Planning.—That the idea of spacing childbirth is gaining support is evident from the increased number of persons who are attending family planning clinics (*Pharmaceutist*, vol. 5, Nov., 1959). On the average, over 14,550 people attend these clinics every month in the state of Uttar Pradesh. From Sept. 1, 1958, to Aug. 31, 1959, 2,123 persons were voluntarily sterilized at these clinics, which render free service to all. Of this number the women outnumbered the men six to one.

NORWAY

Comparison of Drugs for the Relief of Labor Pain.—The pain-relieving effect of 100 mg. of meperidine and 30 mg. of dihydrocodeine were compared in 419 women during labor by Lund and Lind (*Acta anaesth. scandinav.*, supp. 2, pp. 41-48, 1959). The analgesic effects of the drugs were rated as good when more than 50%, fair when 50%, and poor when less than 50% relief from pain was achieved. When the total number of doses for each drug were compared, meperidine gave good relief in 64.2% as compared to 41.4% when dihydrocodeine was used. The authors concluded that 100 mg. of meperidine was far from being an ideal analgesic in childbirth, although it is regarded as much safer than morphine. This belief has prevailed in spite of the fact that the respiratory depression caused by meperidine was as severe or more severe than that caused by equianalgesic doses of morphine. In spite of the strict indications for the use of analgesics in the present series, the newborn infants seemed to have been affected to some extent by the use of meperidine. No such effect could be demonstrated in the infants whose mothers had received dihydrocodeine.

UNITED KINGDOM

Call To Drop Patients' Fee.—A call to the government to abolish all charges to patients using the National Health Service was made by the councils which administer the family doctor, dental, pharmaceutical and ophthalmic services. In a memorandum to the Minister of Health, the Joint Committee of Associations of Executive Councils says the charges are preventing people from having necessary treatment. They are causing hardship, particularly to the older people and those with large families. When it was introduced in 1948 the Health Service was free of charge, with a few minor exceptions. Beginning in 1952, charges have been introduced for medicines and appliances, dental treatment, and glasses, but the comparatively small income derived from patients' charges is outweighed by the disadvantages inherent in the system, particularly the deterrent effect on persons requiring treatment. Estimated total gross Exchequer expenditure on the Health Service for the United Kingdom in the year ended on March 31 was 1,954 million dollars. Patients' payments were expected to amount to 80.6 million dollars or about 4%. Receipts from Health Service contributions, introduced in 1957, were put at 300 million dollars, or just over 15%.

Prophylactic Use of Isoniazid in Infants.—Infants are the most susceptible of all persons to tuberculous infection, and in countries with advanced medical and social care separation of newborn infants from tuberculous mothers is practiced whenever possible, and the infants are artificially fed. In primitive communities, however, the artificial feeding of infants is difficult and hazardous, and if they are not breast fed many of them die from gastroenteritis. Dormer and co-workers in Durbin, faced with the appalling mortality of African infants separated from their mothers, decided to treat with isoniazid all babies born in hospital of mothers with active tuberculosis (*Lancet* 2:902, 1959). The mothers were allowed to nurse their babies if they were well enough to do so. A series of 98 newborn infants were kept in cribs by their mothers, and from birth until the age of 6 months they were given 25 mg. of isoniazid in syrup daily. After six months the dosage was increased to 50 mg. twice daily. No adverse effects on the infants were noted. All but six of them were breast fed, and the mothers who were well enough helped with the care of their children. All the mothers had active pulmonary tuberculosis, and no special precautions were taken to prevent infection. Tuberculin tests were made monthly and roentgenograms of the chest every two months.

Seven of the children became tuberculin positive, but in four of them this was due to inadequate medication with isoniazid. Apart from two deaths there was no evidence of deterioration in the mothers after pregnancy or during lactation. The authors concluded that isoniazid given prophylactically to these newborn native children can almost completely protect them from tuberculosis, but infants so protected do not develop immunity and, as soon as the drug therapy is stopped, are likely to develop the disease. BCG vaccine was not given, as tuberculin conversion was the most important method of detecting infection. It is proposed in the future to give isoniazid-resistant BCG vaccine to all infants before they leave the hospital.

Antibiotics Help Life Insurance.—Many applicants for life insurance who have suffered from what were formerly grave, and often fatal, maladies can now be accepted after recovery, at first class rates, according to Dr. T. W. Preston. Pneumonia, meningitis, and various forms of septicemia are now readily brought under control. Osteomyelitis, in its chronic form, before the era of antibiotics, made the subject a poor insurance risk. These now respond to penicillin therapy immediately, in most cases. One of the most revolutionary changes is in the attitude toward venereal disease. A history of gonorrhea is now no bar to first class acceptance, and with satisfactory evidence of a cure and a negative blood test result, there is now no reason why the syphilitic patient should not be accepted at standard rates after two years. Records of a series of 3,277 cases of pulmonary tuberculosis accepted for insurance between 1947 and 1957 showed that only 7 persons died from tuberculosis and 19 from other causes. This gave a mortality well within the limits of expected rates. Patients who had suffered from tuberculosis of organs other than the lungs are usually acceptable for insurance after a few years. Similar considerations apply to several types of anemia. Experience has not, however, encouraged a more liberal outlook in the acceptance of patients with peptic ulcer. Those with heart disease and cancer are still not insurable.

The Hospital Service.—In a debate on the hospital service of Britain in the House of Lords, Lord Stonham attacked the Treasury and the bureaucracy of the Ministry of Health. He said that the achievements of the ordinary regional hospitals had been made against a disgraceful background of exploitation and parsimony. Less money is being spent on health now than before the war. It has been possible to spend less and do more work only by relying on the traditions, goodwill, devotion, and, indeed, the sweated labor of those who work in the National Health Service. The country is therefore still enjoying a first-class service on second-class payment. The goodwill that enables it to do this is fast running out. Lord Stonham said that only 3.5% of the total expenditure went for maintenance. This resulted in low standards of cleanliness in many hospitals, particularly in London. It is ludicrous for the Ministry to send out directives on the prevention of hospital cross-infection if it cannot keep the hospitals clean. Lord Stonham also asked for a fair deal for ancillary and nonmedical staffs.

Viscount Waverley, a physician at the Royal Berkshire Hospital, said that the outpatient clinics, special departments, and wards were overcrowded. The turnover of patients had been speeded up so much that there was a risk of staff breakdown from fatigue and of inadequate investigation and treatment. Another result was a shortage of nurses, physiotherapists, radiographers, and technicians. Valuable original work was not fostered by the present conditions in the health service. The hospitals deserved greater support. A massive program of new hospital construction was needed. The present prospects were disappointing.

Hypertension.—An epidemiologic survey on persons with high blood pressure without any evident cause was made by Morrison and Morris, who examined the blood pressure and family history of over 300 London bus drivers (*Lancet* 2:864, 1959). The blood pressure of about half the men fell within normal limits, that is, not higher than 150 mm. Hg systolic. The parents of this group of men lived to the age of 65 years or longer. By contrast the remaining group of drivers had parents who died between the ages of 40 and 64 years. These men had a bimodal distribution of blood pressure, about 50% having a peak at about 140 mm. Hg, while the others had a hypertensive peak at about 175 mm. Hg.

As would be expected the systolic pressure of all drivers rose as they grew older from an average of 147 mm. Hg for those 45 to 54 years of age to 158 mm. Hg for those 55 to 60; but the systolic pressures of the drivers in the 55-to-60-year age group whose parents had lived into old age showed the same distribution as those of their fellow workers of 45 to 54 years of age. Thus the average blood pressure of this group of older men did not rise significantly with age. The men with a parent who had died in the fifth or sixth decade of life could be classified into two groups, those in whom the first peak of blood pressure occurred when they were between the ages of 45 to 54 and ages 55 to 60 years and those whose blood pressure reached a second hypertensive peak when they were aged 55 to 60 years. The average rise of pressure during the fifth and sixth decade of the lives of these men seemed to be due not to any general or physiological rise but to the presence of a few subjects from families with high blood pressure. There were substantially more bus drivers than conductors with high blood pressure. The authors concluded that a rise in blood pressure is a disease, since it lowers the expectation of life. These studies showed that hypertension is a strongly hereditary syndrome possibly transmitted by a dominant gene.

Anthrax.—A committee set up to investigate anthrax reported (Report of the Committee of Inquiry on Anthrax, Command 846, Her Majesty's Stationery Office, 1959) that the incidence and mortality of this disease have fallen steeply since the beginning of the century. Reports of cases have dropped by 50%. The mortality has been greatly diminished due to effective chemotherapy, but the decline in anthrax has not been equal in all the industries using potentially infected materials. The disease has practically disappeared from industries in which most of the cases occurred in the past, that is, in those in which wool and hair are used. The biggest problem remains in industries in which hides and skin are handled. The industries in which these are used show no marked reduction in the incidence of external anthrax. The disease has occurred more frequently in those industries in which bones and bone meal are used. Half the fatal cases reported recently were due to handling these materials.

The committee recommended the control of imports and compulsory disinfection of such materials as goat hair, mohair, and cashmere. Materials should be sterilized, and special washing facilities should be provided where goods that may convey anthrax are handled. Workers who may be exposed to anthrax should be issued a card which they should show any doctor who sees them because of suspicious looking lesions, so that the doctor will consider the possibility that the patient has anthrax. The Factory Inspectorate and the Health Service should insure early reference of suspected cases to a doctor. Practitioners and hospitals in areas where workers might contract anthrax should be specially warned of the danger. Report of every case of anthrax should be made compulsory.

Life of the Blood Platelet.—The various methods used for estimating the lifespan of blood platelets before radioisotopes were used did not yield consistent results. Alfos and co-workers (*Lancet* 2:941, 1959) used a method that depends on diisopropylfluorophosphonate labeled with the radiophosphorus (DFP^{32}). This combines with the esterases in the platelets. The DFP^{32} was dissolved in peanut oil or isotonic sodium chloride solution, and 0.4 to 1.3 mg. were injected intramuscularly. Each milligram of material had an activity of between 45 and 200 μc. Blood was withdrawn by vein daily until the platelet activity was too low to measure. Platelets were separated from the blood by allowing it to stand for 30 to 60 minutes at 0 to 4 C, and dextran was added to sediment the erythrocytes. The supernatant plasma containing platelets and leukocytes was centrifuged. After repeated centrifugation the platelet count was determined and the specific radioactivity was estimated. The lifespan of the platelets was deducted from a plot of the DFP^{32} content, expressed in micrograms per 5×10^{12} platelets against time.

The life span of normal blood platelets was considered to be 8 to 10 days. The platelets in the blood of patients with the reticuloses (Hodgkin's disease and lymphosarcoma) were normal or slightly reduced. They were also slightly lower than normal in patients with localized malignant tumors. In patients with polycythemia the life span of the platelets was reduced when the peripheral platelet count was low and increased when it was high. The life span of the platelets was longer in patients with thrombocythemia, probably because of some mechanism for their removal which was impaired by the disease. The improvement in the clotting and the reduction of the platelet count after P^{32} therapy confirmed the intimate connection of the platelets with the bleeding tendency. The reduced life span of the platelets may result from reduced vitality because of interference with megakaryocytic maturation, increased function of the spleen, and the presence of autoantibodies.

Hospital Cross Infection.—Elek and co-workers reported a high incidence of whitlows in hospital nurses, which they attribute to cross-infection with the virus of herpes simplex (*Lancet* 2:871, 1959). Soon after the establishment of a hand clinic 54 cases were quickly reported among the nursing staff. The lesion started as a small area of irritation near the nail and progressed to deep vesicles which coalesced, giving a honeycombed appearance. The vesicles remained localized or spread by crops of fresh vesicles, leading to superficial tissue destruction which spread around the nail and fingertip or under the nail. At a later stage the appearance suggested a whitlow with pus under the cuticle. The lesions were painful, showed a tendency to spread for about 10 days, and took a further week or 10 days to resolve. When the lesions were incised they became secondarily infected with Staphylococcus pyogenes, usually of the type found in the patient's nose or of the type prevalent in the hospital. Bacteriological examination of unbroken vesicles showed the presence of the virus of herpes simplex in nearly every case.

Whitlows appear to be a hitherto unrecognized form of herpetic infection. In this outbreak the two possible sources were patients with herpetic lesions and symptomless salivary carriers of the herpetic virus. The nurses worked mainly in a neurosurgical unit, and it was found that after brain operations symptomless herpetic infection of the saliva of patients was comparatively common. These symptomless carriers were undoubtedly responsible for the soiling of the nurses' hands with infectious material. Almost half of the nurses in the hospital were found to be susceptible.

No Budget for Disease Prevention.—The Minister of Health admitted in the House of Commons that his Ministry had no funds to pay specialists for the prevention of disease. It can only pay for the cure of illness once it has occurred. This has resulted in a London hospital being short of funds. An Occupational Health Unit was opened at the Central Middlesex Hospital, London, three years ago, and the Nuffield Trust agreed to support it financially until the end of 1959. The unit was used by about 40 industrial organizations who were enthusiastic about its value to their workers. Research into the effects of work, fatigue, and working conditions on health was done. The Ministry of Health cannot support the unit financially. The matter has caused heated discussion in the House of Commons, where a Labor member urged amendment of the National Health Service Act to enable specialists to practice preventive as well as curative medicine.

Griseofulvin.—Beare and Mackenzie used griseofulvin to treat 19 children who had Microsporum canis infection (*Brit. M. J.* 2:1137, 1959). Infections of the scalp hair by M. canis offered certain advantages in a trial of a new drug since its effect could be observed by the fluorescence of infected hairs under Wood's light. Moreover, the condition is uninfluenced by topical treatment. The children were given 0.25 Gm. of griseofulvin three times daily, for an average period of 6 weeks (range 3 to 10 weeks). The affected area usually became completely nonfluorescent under Wood's light within three weeks of treatment. By contrast, cultures taken from hair samples, scales, and hair debris continued to be strongly positive, in some patients for many weeks. The criteria of eradication of infection were at least three consecutive negative cultures and negative microscopic findings at weekly intervals for 16 weeks. This long follow-up was necessary because one child was still infected after 14.5 weeks. Absence of fluorescence under Wood's light could not be accepted as evidence of freedom from infection. Using such strict criteria the results obtained with griseofulvin were not as favorable as those reported by other workers.

No toxic effects were seen from the drug, although it is said to be a mitotic poison when given in large doses to animals. Fungal invasion of hair ceases soon after the drug is given, but infected debris remains in the scalp and from it organisms can be recovered, in some cases three months or more after beginning treatment. As the condition cures itself spontaneously in this time the results obtained with griseofulvin cannot be considered particularly impressive. Indeed on this evidence it would appear that in itself the antibiotic is insufficient to cure ringworm of the scalp in a short period. It was thought that eradication of the organism from the scalp might be hastened if it were washed or scrubbed repeatedly and a fungicide applied locally as well as given orally.

Barlow and co-workers used griseofulvin to treat 34 patients with persistent fungal infections of the skin (*Brit. M. J.* 2:1141, 1959). The infecting organisms were Trichophyton rubrum, Trichophyton verrucosum, Trichophyton mentagrophytes, and Candida albicans. No appreciable hematological effect was noted, but a few patients complained of headache, nausea, and malaise, and five patients developed an erythematous rash. Three patients were unable to tolerate the drug. Griseofulvin was ineffective against infection with C. albicans, Malassezia furfur, and T. verrucosum, but it did benefit patients infected with other dermatophytes, including T. rubrum. While most patients improved, in only one was the infection eradicated. Since griseofulvin is fungistatic and not fungicidal it may be necessary for the adequate treatment of nail infections to give the antibiotic for long periods while the nail grows out. This may take a year for infections of the nail of the big toe.

Treatment of Tetanus with Chlorpromazine.—The successful treatment of tetanus with chlorpromazine, first reported by Laurence, was confirmed by Shanker and Mehrotra (*Brit. M. J.* 2:1150, 1959). This drug, besides inhibiting motor activity and diminishing the tone of skeletal muscle, has a sedative and tranquilizing action. In addition, it potentiates the action of hypnotics and sedatives. These properties make it particularly suitable for the relief of the muscle spasms of tetanus. The authors treated 30 patients who had tetanus, one half being given chlorpromazine and the other half paraldehyde. The general nursing care and the use of antitoxin was the same in both groups. All patients were given penicillin prophylactically. Reflex spasms were dramatically controlled within 30 minutes and did not recur for at least four hours after an injection of chlorpromazine. There were three deaths in the group treated with chlorpromazine and seven in the control group. The results were even better than these figures would suggest, as there were more serious cases in the chlorpromazine-treated group than in the controls. A cure rate of 92% was recorded in the chlorpromazine-treated patients who survived for more than 24 hours. The corresponding figure for the control group was 62.6%.

Anti-G Suit for Hypotension.—A 67-year-old woman suffering from cerebral anoxia due to persistent hypotension was treated by means of a jet pilot's anti-G suit. The woman had been bed-ridden because if she stood or even sat up she blacked out from the reduced flow of blood to the head. The pressure of the G-suit around the legs and waist redistributed peripheral blood to the upper part of the body. After putting on the suit the patient was able to stand and sit without loss of consciousness for the first time in six months.

Blood Pressure and Age.—Five years ago Miall determined the blood pressure in a random sample of the general population and all the first degree relatives of the population of Rhondda Fach in Wales. He has followed this up to examine the effect of age and other factors (*Brit. M. J.* 2:1204, 1959). Reexaminations were made under identical conditions on 1,114 (99.6%) of the 1,119 subjects seen originally and still resident within 25 miles of the valley. It was found that over the five-year period the blood pressure of the women remained the same, but that of the men increased in all age groups. The results suggest that when full allowance is made for age, arterial pressure may be increasing in middle-aged men.

This trend is occurring to a greater extent in men previously engaged in heavy work, although they still have lower pressures than those previously in light occupations. The differences in the mean systolic and diastolic pressures at 45 years of age between men in light occupations and those in heavy occupations were 10 and 8 mm. Hg respectively. Blood pressure was found to correlate with family size in both the men and the women; the larger the family the lower the pressure. This trend was clear-cut only in the reproductive age, which was taken to be 15 to 45 for women and 15 to 50 for men. In several of the age groups the mean arterial pressure recorded in the follow-up period fell in the women who had had children, whereas it did not fall in those who had not.

The effect of taking added salt in the diet was studied. In view of the effect of salt restriction on the blood pressure of hypertensives it was expected that a high salt intake would be associated with a higher arterial pressure than a low salt intake. This was not so. In fact the converse was found, women who added salt to their cooked meals being found to have lower blood pressures and smaller pulse pressures than those who did not. The former group were also lighter. No comparable differences were found in the men.

Infant Feeding.—In a report by the Medical Research Council (Weight Gains, Serum Protein Levels, and Health of Breast Fed and Artificially Fed Infants, M. R. C. Report 296, Her Majesty's Stationery Office, London, 1959) normal standards of weight and hemoglobin, serum albumin, and globulin levels were established for the first 18 months of life from studies on 521 full-term and 223 premature infants. The artificially fed infants were given full cream dried milk made up with water and added sugar. The incidence of infection was found to be the same in both breast fed and artificially fed infants, and there was no significant difference in the weights of the two groups. It was concluded that breast milk is inadequate for premature infants, whose protein needs cannot be satisfied with it.

Serum albumin and globulin levels in the normal infant were found to be unaffected by the type of feeding. The serum gamma-globulin level was found to be higher at birth than in adults, but it dropped shortly after birth and reached its lowest level in the fourth or fifth month. Part of the gamma globulin is synthesized by the fetus, and this synthesis continues after birth. Dilution in an expanding plasma volume may account for the falling gamma-globulin level, which may remain relatively constant during the first three months of life. Although the report recognized that there was no physiological or nutritional advantage in breast feeding, it pointed out that it is highly desirable because of the natural emotional relationship that it establishes between mother and child.

Postoperative Venous Thrombosis.—Pulmonary embolism and thrombosis of deep veins of the legs are relatively common causes of illness and death in those over 50 years of age confined to bed for any length of time after operations or for illness. Sevitt and Gallagher stated that at the Birmingham Accident Hospital pulmonary embolism was found at 20% of autopsies and was the cause of death in 40 to 50% of elderly patients who died from a fracture of the femur, tibia, or pelvis. In the same hospital thrombosis of the deep veins of the leg occurred in 60% of fatally injured patients without a pulmonary embolism. As thrombosis is a silent process and widespread postoperatively in elderly persons, the authors made a controlled clinical trial to observe the effect of the anticoagulant phenindione, when given prophylactically, on the incidence of postoperative thrombosis and pulmonary embolism in the elderly (*Lancet* 2:981, 1959). The trial was restricted to patients over 55 years of age with either a subcapital or intertrochanteric fracture of the femur because of the high incidence of embolism and thrombosis in such patients. From the point of view of a controlled trial they formed a homogenous group with a fairly common, single, and almost standard trauma, similar age and sex distribution, and a high death rate, which would serve as an effective yardstick in assessing the value of the prophylactic action of an anticoagulant.

In a series of 300 patients phenindione was given to half and the rest served as controls. The drug was given on the day of admission or before the operation for a mean period of five weeks and generally until the patient was ambulant. In a few the administration of the drug was continued after the patient left the hospital. The initial dose of phenindione was 200 mg., followed the next day by 100 mg., and subsequently by 25 to 75 mg. daily. Dosage was controlled by the one-stage plasma prothrombin level (Quick), which was maintained at between 15 and 30% of the normal value. Urine and feces were tested for blood if the prothrombin fell to undesirable levels. Patients in special danger of hemorrhage, such as those suffering from melena, hematemesis, hematuria, recent peptic ulcers, or hemoptysis were not given phenindione. The diagnostic criteria used to detect thrombosis or embolism were the same in the treated and control groups. Patients were followed up for at least three months from the time of the fracture, and in fatal cases an autopsy was performed with careful dissection of the lower venous tree, whenever possible.

There were 43 cases of clinically diagnosable thrombosis in the control series (29%) compared with only 4 cases in the phenindione-treated series

(3%), a reduction of over 90% in frequency. The average inpatient stay of the survivors with clinical thrombosis was 54 days in the control series and 42 days in those who received phenindione. Thus, prophylaxis with the latter shortened bed rest and saved lives. None of the phenindione-treated patients developed nonfatal clinical embolism whereas eight of the controls did. A fatal major embolism was found in 17 of the patients in the control series and in 2 of the phenindione-treated group. The two latter deaths occurred after treatment had been discontinued, so that they were not really failures of prophylaxis. No patient had a fatal thrombosis while taking phenindione.

Even more conclusive was a comparison of the frequency of thrombosis in the deep veins of the lower limbs at autopsy. Significant or extensive thrombosis was found in 29 of the 35 control patients (83%) compared with only 3 of the 21 phenindione-treated patients examined (14%). Autopsy revealed that almost 40% of the patients in the control series had developed some form of thromboembolic disease other than deep vein thrombosis, while only 4.7% of the phenindione-treated patients had cases of these diseases, all of which could be explained. The evidence indicated that phenindione effectively prevented thrombosis in veins and eliminated the risk of pulmonary embolism in patients under its influence, provided it was given early, for sufficient time, and under laboratory control.

Drug Publicity.—In a letter to the *British Medical Journal* a group of physicians in Edinburgh, led by Prof. J. W. Crofton, protested strongly against the mounting publicity given to new drugs and new treatments in the national press and over the radio and television. In particular they object to that given to a new treatment for chronic bronchitis with a preparation containing finely divided chymotrypsin and isoprenaline. A press conference was held in London recently by the company marketing it. Press representatives were informed that 60 general practitioners in various industrial areas had tested this preparation. Two of the doctors concerned related their experiences in treating over 200 chronic bronchitics, in whom excellent results were obtained. This press and radio publicity resulted in many chronic bronchitics demanding the new treatment for their complaint.

Prof. Crofton and colleagues considered that the claims made were extravagant on the evidence available. They questioned the statement of the manufacturers that a mucolytic enzyme combined with a bronchodilator produced satisfactory improvement in 71 to 92% of the chronic bronchitics treated. The design of the trial was faulty. It was done in late spring and early summer, when bronchitics improve spontaneously and it was inadequately controlled. In this kind of advertising a pseudoscientific façade conceals an unsound approach to the testing of a new drug. The letter objected to radio and press advertising of new remedies because these media are regarded by the public as authoritative. Many patients who heard the broadcast or read the press reports approached the writers full of hope about the new treatment and begged to have it given to them. These physicians felt compelled to give it a trial in several patients who would have otherwise complained bitterly that they were being denied the benefit of a major therapeutic advance. None of those given the treatment received any noticeable benefit. The doctors urged that the matter be brought to the attention of the British Broadcasting Corporation.

In an editorial the *British Medical Journal* pointed out there was no longer any excuse for any firm to market a product for which a therapeutic advance is claimed until it has been submitted to a carefully conducted controlled clinical trial to establish the claims made for it. In the long run it will be commercially more profitable to the pharmaceutical industry to conduct such trials than to sell poorly tested new drugs in the market place.

Response to Vasodilator Drugs.—Gillespie questioned the value of vasodilator drugs in the treatment of obliterative vascular disease (*Lancet* 2:995, 1959). In patients with this condition he examined their effect on blood-flow in the foot and in calf muscles, their value in augmenting the effect of sympathectomy, and their use in forecasting the result of lumbar sympathectomy. As the blood flow in the foot and calf can be measured the value of vasodilators can be readily assessed. Blood flow in the foot and calf of patients with and without obliterative arterial disease and before and after administering the vasodilator was measured by venous-occlusion plethysmography with water-filled plethysmographs in a constant-temperature laboratory. The drugs tested were tolazoline, phenoxybenzamine, chlorpromazine, and promazine.

Vasodilators increased blood flow to the feet of healthy subjects, but the response in limbs with occluded arteries was different. In patients with unilateral occlusion, vasodilators increased blood flow in the healthy foot but decreased it in most cases in the foot with occluded arteries. Intermittent claudication is prone to such spontaneous variations in severity that the result of clinical drug trials must be interpreted with caution. If vasodilators are to relieve claudication they must increase the blood flow in the muscles. Gillespie found that they decreased the blood flow by 4% in healthy subjects and up to 26% in patients with obliterative vascular disease. The effect of vasodilators on the blood flow of 29 sympathectomized feet was examined. In 25 limbs there was no increase. In some a decrease occurred. The response to vasodilator drugs gave no indication of the probable effect of sympathectomy in occlusive vascular disease, and was of no value as a preoperative test.

CORRESPONDENCE

PEPTIC ULCERS IN CHILDREN

To the Editor:—I am writing with regard to the comment, entitled "Peptic Ulcers in Children," which appeared in THE JOURNAL, Dec. 5, 1959, page 1990. Dr. Tudor states that he is "establishing a registry of children who have peptic ulcers" and requests "anyone who knows of child patients with peptic ulcer, diagnosed either post mortem or roentgenographically," to send him the pertinent data. I wonder if Dr. Tudor is aware how equivocal a roentgenographic diagnosis of peptic ulcer in children is. If he would consult radiologists at any outstanding children's hospital in the country, he would discover that the roentgenographic diagnosis of peptic ulcer in children is extremely rare, frequent diagnosis by less experienced examiners notwithstanding.

Among radiologists familiar with pediatric gastroenterology, such findings as spasm, hypersecretion, and prominent rugae, which are often used to establish the diagnosis, are considered normal in children. It is doubtful whether the establishment of a registry based on equivocal cases would be of any value.

E. J. KEEFFE, M.D.
St. Joseph Mercy Hospital
Pontiac, Mich.

To the Editor:—I appreciate the letter from Dr. Keeffe concerning the difficulties in the diagnosis of peptic ulcers in children. I am aware of the difficulty, since I have been working with this problem for 11 years. The four radiologists on the staff of my clinic are experienced in pediatric radiology. Our radiology residents spend a portion of their time in pediatric radiology at Childrens' Hospital, in Cincinnati. A diagnosis of peptic ulcer is not made unless an ulcer crater can be demonstrated. To minimize exposure of the patient, the fluoroscopic time is sharply limited and reliance is placed on multiple spot films in various projections, including double-contrast examination of the duodenal bulb. Ordinarily, 8 to 12 spot films and 4 roentgenograms are taken during the stomach examination. The best detail is obtained with use of water-soluble contrast agents.

In the last 11 years, over 90 pediatric peptic ulcers have been demonstrated. The youngest patient was one day old. Follow-up examinations at 6 to 12 weeks in the patient with gastric ulcer and in selected patients with duodenal ulcer have demonstrated satisfactory healing. The chief of the department of radiology at the children's hospital in Stockholm reviewed the films during a visit in 1957 and agreed with our findings. We would not make a diagnosis of peptic ulcer from such secondary signs of ulceration as spasm, hypersecretion, or prominent and irregular rugal folds.

AVICENNA

To the Editor:—In THE JOURNAL, Aug. 4, 1945, the filler on page 1003 cites a common error, that of calling Avicenna a "most distinguished Arab physician." Avicenna, or Abu Ali al Hussein ibn Sina, was a Persian, born of Persian parents in 980 A. D., in Khormisan, near Bukhara, then the Persian capital but now in the U. S. S. R. He became physician to several Iranian kings and finally minister to one of them. Of his 283 books, some were in Persian but most of them in Arabic, the language of science at that time, as Latin was to be later. (Yahya Mahdavi: Bibliographie D'lbn Sina, University Tehran, no. 206, in Persian.) Ibn Sina died in 1037 A. D. in Hamadan, the Ecbatana of Alexander's time. An imposing memorial honors him there.

EDITOR'S NOTE: Other items pertaining to Avicenna have appeared in the Correspondence section of THE JOURNAL, May 24, 1952, page 390, and Nov. 1, 1952, page 951.

SHOOTING ACCIDENTS

To the Editor:—The news item, "Report On Shooting Accidents," which appeared in THE JOURNAL, Dec. 19, page 2232, is an excellent example of statistical accuracy that can be misused to substantiate claims of anti-gun enthusiasts that are completely unwarranted by the facts.

The fact that persons aged 15 to 19 constitute only 3% of the total population of the United States, while accounting for about 16% of those fatally injured in firearm accidents, is somewhat irrelevant to the question of whether or not these users might be capable of handling firearms. Much more useful data would be the frequency of accidents in 15-to-19-year-olds in proportion to the total number of man-hours spent in hunting with guns. It appears extremely unlikely that 3% of women or of elderly persons in the total population spend much time with firearms. For that reason, too, a high accident rate would be expected in young men, even though they use the same amount of care and precaution as do other segments of the population.

I recognize that this news item was simply reported from an outside source, but I believe care should be taken in disseminating this sort of information, to prevent its becoming available to persons who will misconstrue the facts and use them to their advantage.

ELEMENTS OF STYLE

To the Editor:—I have read the editorial, "Elements of Style," in The Journal, Jan. 23, page 345. Naturally, I am flattered. I must accept the compliment with some reservation, however, because as a matter of fact I have on occasion made a number of revisions or drafts before I have been satisfied with what I have written. It seems to me that this is bound to be so.

Paul D. White, M.D.

Boston.

I suspect that even a medical Winston Churchill finds it necessary to revise and rewrite some manuscripts.—Ed.

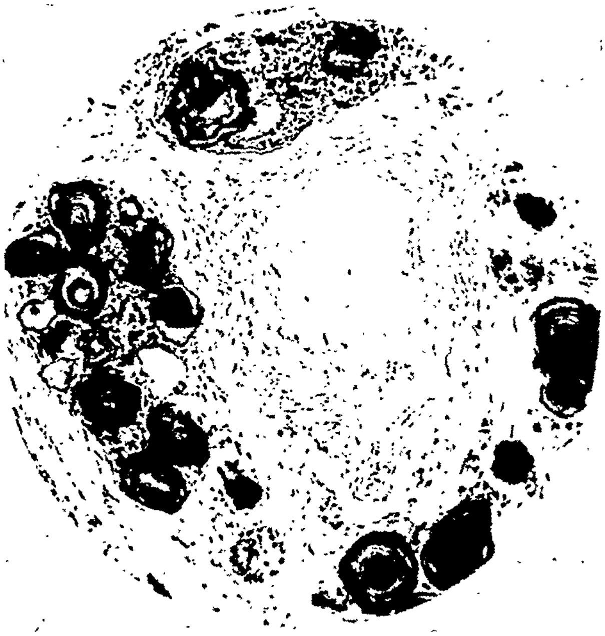
PSAMMOMA BODIES IN CANCER OF LUNG

To the Editor:—In their article on psammoma bodies and cancer of the thyroid (abstracted in The Journal, Nov. 28, page 1901) Klink and Winship stated that these bodies occur in a large percentage of patients with cancer of the thyroid and that "A biopsy specimen of a lung tumor that contains psammoma bodies should suggest the thyroid as a possible primary site." Their statement implies that similar calcific concrements are not apt to be found in patients with cancer of the lung.

Such bodies were found in a patient with primary cancer of the lung, a man aged 26 years whose illness started abruptly with an uncontrollable hiccough. Roentgenologic examination revealed, at the base of the right lung, a well circumscribed dense shadow which merged with the diaphragm. Bronchoscopic examination gave a negative result and the laboratory data were noncontributory. The patient recovered from his hiccough after three days and complained of no other symptoms. The diagnosis of a benign neoplasm was made. The patient was discharged and instructed to report for periodic reexamination.

He remained asymptomatic for about six years. During this time, x-ray examinations failed to show any changes in the dense basal shadow of the right lung, but at the end of this period he had begun coughing and expectorating a large amount of sputum. He complained of mild pain in his chest, loss of weight, and growing weakness. A roentgenogram of the right lung showed an area of density at the base, about 6 cm. in diameter, and multiple nodular densities scattered throughout the lung. The left lung showed several metastases. The patient died about six and one-half years after the onset of symptoms, with signs of cerebral metastases.

The autopsy revealed an epidermoid carcinoma (lymphangiotic type) of the right lung, with metastases to the left lung and to the bronchial lymph nodes. On histological examination the nodular densities observed in the roentgenogram were found to be hyalinized tissue. They contained entrapped cancer cells and round, concentrically laminated concretions, namely, psammoma bodies (calcospherites or microliths). The calcific bodies were confined to the perivascular spaces of small and large pulmonary vessels (see figure), along which the cancer had spread. They were not found in the metastases to the left lung but were present in the metastases to the bronchial lymph nodes. They were not found in the lumens of the air sacs. This case serves to illustrate an instance in which psammoma bodies were found in a primary epidermoid cancer of the lung.



Psammoma bodies and cancer cells in perivascular spaces of pulmonary vein.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Tuberous Sclerosis: A Report of 16 Cases in Two Family Trees Revealing Genetic Dominance. D. Marshall, G. B. Saul and E. Sachs Jr. New England J. Med. 261:1102-1105 (Nov. 26) 1959 [Boston].

The authors' review of the literature on tuberous sclerosis makes it evident that this condition, with the classic triad of mental deficiency, epilepsy, and adenoma sebaceum, is a widespread tissue dysplasia of unknown causation involving all the primitive germ layers. The authors report tuberous sclerosis in a 24-year-old woman and in a 16-year-old youth. Both patients were first seen by ophthalmologists because of diplopia. In the woman, it was the x-ray finding of calcific densities in the brain that first suggested the diagnosis. A ventriculogram revealed intraventricular pressure of over 600 mm. and symmetrical dilatation of both lateral ventricles as well as of the 3rd and 4th ventricles. A ventriculomastoidostomy was done on the right side. After several unsuccessful attempts to maintain patency of the ventriculomastoidostomy, a transventriculofrontal craniotomy on the right side was done, which showed the entire right lateral ventricle and the 3rd ventricle filled with a red, vascular tumor. The tumor was removed. The patient died on the 5th postoperative day. At autopsy, considerable softening and necrosis extending into the hypothalamus and caudate nucleus were observed. Other findings included a defect of the interatrial septum, a leiomyoma of the kidney, and fibromas of the heart, liver, vaginal wall, and lungs. The brain tumor was an ependymoma, grade 3. The family history revealed 12 members in 3 generations with tuberous sclerosis, 7 of whom were severely affected and 5 were mildly affected. Examination of the second patient revealed bilateral papilledema, adenoma sebaceum of the face, café-au-lait spots, patchy leukoderma, and periungual fibromas. Ventriculography showed a tumor of the 3rd ventricle, which was removed surgically. Microscopic examination of the operative specimen revealed an astrocytoma. The patient died on the 10th postoperative day. The family history revealed that the patient's mother had tuberous sclerosis with adenoma sebaceum of the face and intracranial calcification and seizures. She too had an astrocytoma of the 3rd ventricle, which had been removed in 1932, and she is still living. The patient's grandfather also had had adenoma sebaceum and subungual fibromas.

Although some of the family members of the first patient could be described as showing severe generalized involvement, few exhibited the classic triad of tuberous sclerosis. More often only one or two of the classic findings were present, usually in association with some other morbid condition. The genetic significance of making the diagnosis of tuberous sclerosis in persons who have only the "forme fruste" type of the disease is pointed out, and it is emphasized that any medical specialist may be the first to see such a patient. This series brings to light a group of patients who have tuberous sclerosis with the relatively rare association of brain tumors. The necessity of following children of involved parents for subsequent development of signs or symptoms of tuberous sclerosis is emphasized. The genetics of the lineage in the families of the 2 patients are discussed, and the mode of inheritance is shown to be by a dominant gene that can be affected by an independent pair of modifying genes.

Acute Anoxic Cardiac Failure in Pulmonary Heart-Disease. G. Kellaway. Lancet 2:768-773 (Nov. 7) 1959 [London].

The author reports on 32 men and 12 women with acute anoxic cardiac failure, due to pulmonary heart disease as the sole causative factor, and right ventricular strain, as revealed by the electrocardiogram, who were admitted to the department of cardiology of the Royal Infirmary in Edinburgh. These patients represented 13% of 334 patients who were admitted to this hospital with cardiac failure uncomplicated by other cardiovascular disease. For at least 3 days the patients were maintained in an oxygen tent. Apart from treatment with mechanical respirators, there is no readily available method of restoring arterial oxygen levels to normal without the danger of carbon dioxide narcosis. The author's method of administering continuous oxygen therapy, without permitting carbon dioxide narcosis to supervene, consisted of intramuscular injections of 5 cc. of nikethamide and of 30 mg. of amiphenazole every 2 hours. The injections of nikethamide and

The place of publication of the periodical appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by persons in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1956 to date for English language and 1958 to date for foreign language journals. No photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

amiphenazole were alternated, so that the patients received a respiratory stimulant every hour. Signs of carbon dioxide narcosis were considered as an indication for more frequent doses of respiratory stimulants. Antibiotics were given to help overcome the respiratory infection. Sedation was necessary in all the patients, and meperidine (Demerol) was given in doses of 50 to 150 mg. Those with clinical evidence of moderately severe carbon dioxide narcosis also were given 2 mg. of levallorphan per 100 mg. of meperidine to counteract possible depression of the respiratory center.

Eighteen of the 44 patients, with an average age of 60 years, were treated according to this method. Five patients died. Satisfactory oxygenation and clinical improvement were evident in 13 patients within 3 days of the institution of treatment, and usually administration of respiratory stimulants was unnecessary after the 5th day. Oliguria persisted for several days after arterial oxygen saturation was raised to normal levels. During this period edema increased despite clinical improvement. The results suggest that the administration of oxygen should be continued until diuresis begins. When discharged from hospital, all 13 patients were free from cardiac failure. The absence of deaths due to carbon dioxide narcosis and the improvement in immediate and more distant prognosis suggest that this is a good method of managing these patients.

Hypercalciuria in Hepatolenticular Degeneration (Wilson's Disease). R. B. Litin, R. V. Randall and others. Am. J. M. Sc. 238:614-620 (Nov.) 1959 [Philadelphia].

Five patients with hepatolenticular degeneration (Wilson's disease) were observed at the Mayo Clinic. The diagnosis of this disease had been established by the findings of neurological manifestations, typical Kayser-Fleischer rings, and increased urinary excretion of copper and alpha-amino nitrogen. There was no familial history of hepatolenticular degeneration for any of the patients, and none of them had received treatment for this disease for 1 to 4 months prior to this study. The urinary excretion of calcium was measured in each patient over a 3-day period, during which the patients were given a diet containing a known amount of calcium. Three successive specimens of urine were collected from each patient over 24-hour periods, and analyzed the day the collection was completed.

Under the diet used in this study, a value of urinary calcium above 170 mg. per 24 hours can usually be considered to be abnormal. By this criterion, 4 of the 5 patients had hypercalciuria. One patient had nephrocalcinosis and a history of nephrolithiasis, and another had a stone in the left kidney. Excretory urograms in 2 of the other patients were normal. The cause of the hypercalciuria was not determined. The authors suggest that hypercalciuria in hepatolenticular degeneration may represent another tubular defect inherent to the disease.

Clinical Observations Regarding Xanthelasma. J. B. Vacca, W. A. Knight Jr. and G. O. Broun Sr. Ann. Int. Med. 51:1019-1031 (Nov.) 1959 [Lancaster, Pa.]

Xanthelasma or xanthoma palpebrarum has been reported more frequently than any other type of cutaneous xanthoma. It has been noted to occur in many types of xanthomatosis, especially with xanthoma tuberosum and xanthoma disseminatum, but is believed not to occur with the xanthomatosis associated with essential hyperlipemia. In order to determine the clinical significance of xanthelasma, 51 consecutive persons (patients, relatives of patients, visitors, employees, outpatients) with xanthelasma observed in the environs of a general hospital by members of the house staff, student body, and attending staff were examined by one of the authors during a period of about 18 months. A complete history and a physical examination were obtained in all 51 persons, with particular emphasis on the following: how long the xanthelasma had been present; size of the xanthelasma; presence of xanthoma elsewhere; evidence of angina pectoris, myocardial infarction, congestive heart failure, heart murmurs, hypertension, or diabetes mellitus; menstrual history; evaluation of retinal, cerebral, and peripheral vascular status; height and weight; nutritional status; family history of xanthelasma or xanthoma elsewhere, coronary artery disease, and vascular disease generally.

Thirteen of the 35 women in the group of 51 persons were more than 40 lb. (18.1 kg.) overweight, whereas only 1 of the 16 men was that much overweight. Of the 35 patients who were adequately tested, 12 had clinical or latent diabetes mellitus of the adult type. Thirty-one of the 35 women with xanthelasma were postmenopausal at the time of this study, and 9 of these had had their menopause before the age of 45 years.

Seventy-three per cent of the entire group of 51 persons had a cholesterol level greater than 300 mg. per 100 cc., and 79% of those tested had mild to moderate elevations of total blood lipids. Evidence of coronary artery disease was present in 69% of the men and in 43% of the women. Peripheral vascular disease occurred in 20% and cerebrovascular disease in 8% of the entire group of patients. The occurrence of cachexia or a wasting disease in a person with xanthelasma was associated with a lower elevation of blood lipids. There were indications of a general relationship between the size of the xanthelasma and the cholesterol level. A striking variation of serum cholesterol levels was observed in many of the patients. The degree of fluctuation seemed to be related to the mean cholesterol level. A family history of xanthoma (including xanthelasma) or of prominent vascular disease was obtained in a minority of the persons studied. There were 5 persons in whom there was a definite family history of xanthelasma in association with cardiovascular disease; in addition, one person's brother was known to have tendon xanthoma and to have died in middle age of a myocardial infarction. Besides these, there were 3 persons who had a striking family history of cardiovascular disease without any definite knowledge of the presence of xanthelasma or other xanthoma in the affected relatives.

Takayashu's Syndrome: Pulseless Disease. P. Kølle-Jørgensen. Ugesk. læger 121:1694-1695 (Oct. 29) 1959 (In Danish) [Copenhagen].

Sixteen cases of pulseless disease (Takayashu's disease) or arteritis brachiocephalica have been reported from Scandinavia, 3 of them from Denmark. The etiology is not known. Increased sedimentation reaction is thought to be a constant feature in the disease, which is marked by a progressive closing of the large arteries that proceed from the aortic arch. Pathologically, there are fibrous hyperplasia of the intima and chronic infection in the media and the intima. The symptomatology varies, depending on the arteries affected and the degree of closure. The disease occurs almost exclusively in women; only 3 cases in men have been reported in the European literature. The prognosis is unfavorable, but the course is often prolonged. The case described is unusual in being unilateral and in a man. Examination showed increased sedimentation reaction and absence of pulsation in the right arm and on the right side of the neck. The diagnosis was verified by aortography. Examination of the serum protein showed normal conditions. As the patient's main difficulty was due to thromboses, regarded as secondary to the arteritis, ambulant long-term anticoagulant treatment was instituted.

Results of Treatment of Malignant Hypertension: A Seven-Year Experience in 94 Cases. M. Harington, P. Kincaid-Smith and J. McMichael. Brit. M. J. 2:969-980 (Nov. 14) 1959 [London].

Eight years have elapsed since the introduction of ganglion-blocking agents in the treatment of severe hypertension. The present report deals with malignant hypertension under this treatment, and the course of the treated cases is compared with a control series from the same London hospital over the period 1935-1956. The series comprises 82 patients with malignant hypertension. This total includes all patients seen at this hospital in the years 1951-1957, inclusive, in whom malignant hypertension was diagnosed and in whom treatment with ganglion-blocking drugs was attempted (12 were not treated because they were in the terminal stages when admitted).

The expectation of life of the treated patients was increased by a factor of 6 to 8 times that expected from the control series. Prolonged survival was particularly seen in patients whose renal function was normal or only slightly impaired. Death was most frequently due to uremia; death from heart failure was considerably diminished in the treated group. The benefits of treatment were most pronounced on retinitis and in heart failure. Improvement in the electrocardiogram was seen in one-third of the cases; reduction in cardiac size occurred somewhat less frequently.

Renal function tended to remain stationary or to improve slightly in patients with an initial blood urea level below 80 mg. per 100 cc.; where renal impairment was more severe than this, progressive deterioration was the rule. Patients with neurological complications did not derive much benefit from treatment. Atherosclerosis was a limiting factor in the success of treatment, particularly in older patients. A survey of the histological lesions in the kidneys showed that, after treatment with hypotensive drugs, the main changes were a conversion of cellular intimal hyperplasia in the interlobular arteries to fibrous intimal thickening and a "healing" of fibrinoid degeneration to hyaline and fibrous tissue. There was some correlation between the degree of narrowing of the interlobular arteries at the start of treatment and prognosis.

Whirlpool-Induced Purpura in Anaphylactoid Purpura. H. Hoefle Jr. and R. C. Williams Jr. Am. J. M. Sc. 238:610-613 (Nov.) 1959 [Philadelphia].

A case of anaphylactoid purpura presenting unusual diagnostic features is reported. The patient, a 23-year-old Air Force staff sergeant, was admitted to the USAF Hospital in Wiesbaden, Germany, complaining of pain and stiffness in the left hip after a fall. Laboratory examinations, roentgenograms, and electrograms were normal. In spite of therapy with bed rest, aspirin, and physical therapy, the patient had a temperature of 100 to 100.6 F (37.7 to 38 C) and pain, swelling, heat, and stiffness of the joints. These symptoms gradually abated, but petechiae and purpuric spots appeared on the anterior surface of the legs between the knees and ankles. Repeated blood counts, bleeding and clotting times, and Rumpel-Leede tourniquet tests were within normal limits. The patient was transferred to another hospital because of petechiae and continued to suffer from moderate arthralgia. Five weeks after the onset of the disease, a whirlpool treatment was added to the salicylate therapy. Shortly after immersing his legs in the whirlpool bath, the patient noted a recurrence of petechiae over his lower legs. The same occurred with additional baths. Concomitantly the results of all blood examinations were within normal limits.

It was felt that this patient had Henoch-Schönlein's syndrome, or anaphylactoid purpura associated with mild and recurrent arthralgia. He was treated symptomatically with salicylates and graduated exercises, and recovered his joint function over the next 6 weeks. During this period the petechiae also subsided. The patient returned to duty and during the next 5 months had no recurrence of symptoms, not even with repeated whirlpool immersion. It was concluded that the combination of heat and mechanical trauma induced purpura in the capillary beds exposed to the whirlpool bath. This effect is not present in normal subjects and was not present in the patient after recovery from his acute illness. The findings suggest that whirlpool bath immersion may be of value in assessing capillary fragility when other tests of capillary integrity are normal.

Value of Laboratory Tests in the Diagnosis of Anicteric Metastatic Hepatopathies. A. J. Piccaluga, R. M. Laplacette and others. Prensa méd. argent. 46:1174-1177 (May 8) 1959 (In Spanish) [Buenos Aires].

Fourteen anicteric patients with metastatic tumors of the liver underwent laboratory tests of bilirubinemia, cholesteremia, alkaline phosphatasemia, turbidity, and flocculation as well as paper electrophoresis. The diagnosis of the primary tumor was established surgically in 7 patients, by puncture biopsy in 6, and clinically in 1. Only the findings of the first examination of the 14 patients are considered in this report. The most marked changes were those in phosphatasemia, albuminemia, and globulinemia. The phosphatasemia values exceeded 6 Bodansky units in 10 patients, and exceeded 20 units in 7. Hypoalbuminemia was found in 93% of the patients. There was an increase in alpha-1 globulin and a marked increase in alpha-2 globulin which reached above normal values in all 14 patients studied. The authors conclude that the determination of alkaline phosphatasemia and the findings of paper electrophoresis have a definite value in the detection of secondary tumors of the liver. One of the causes of the elevation in alkaline phosphatasemia is the compression and distortion of the intrahepatic biliary ducts by tumoral nodules.

Factors Controlling Hemopoiesis: Experimental Observations on Their Role in Polycythemia Vera. J. W. Linman, F. H. Bethell and M. J. Long. Ann. Int. Med. 51:1003-1018 (Nov.) 1959 [Lancaster, Pa.].

Until recently little was known concerning the manner in which erythrocytic equilibrium was maintained or restored. During the last few years, studies in many laboratories have established the existence of a humoral erythropoietic regulatory mechanism, and evidence is now available which suggests that the formation of other hemic elements may be subject to similar controlling factors. Studies carried out by the authors indicate that 2 humoral factors exert basic regulatory control over erythropoiesis. A relatively thermolabile, ether-insoluble agent augments hemoglobin synthesis, whereas a thermostable, ether-soluble factor appears to govern the mitotic or proliferative activity of erythrocytic precursors. This humoral mechanism most likely constitutes the primary erythropoietic stimulus, and is apparently responsible for the maintenance of the normal erythroid steady state and for the accelerated erythropoiesis which accompanies hypoxic and certain types of anemic hypoxia. The presence of enhanced plasma erythropoietic activity in patients with polycythemia vera, which occurs in the absence of hypoxia and persists irrespective of the institution of specific myelosuppressive therapy, supports the thesis that the humoral factors are of etiological importance in this disorder.

The ether-soluble or thermostable fractions of plasmas from patients with polycythemia vera also possess thrombocytic and granulocytic stimulatory activity. It is suggested that batyl alcohol, a substance which also induces erythrocytosis, thrombocytosis, and granulocytosis in normal rats, may be closely related to the thermostable, ether-soluble plasma factor. Although the precise significance of the hemopoietic effects of batyl alcohol and of the plasmas of patients with polycythemia vera is still speculative, observations lend credence to the theory that all aspects of hemopoiesis are under humoral regulatory control. A single agent may affect (although not to the exclusion of other mechanisms) the formation of all hemic elements, and may explain the thrombocytosis and leukocytosis associated with such conditions as polycythemia vera, acute hemorrhage, and hemolysis. Further study of the factors controlling hemopoiesis should clarify certain currently obscure hematological disorders and responses.

Marfan's Syndrome and the Weill-Marchesani Syndrome in the S. Family. D. Bowers. Ann. Int. Med. 51:1049-1070 (Nov.) 1959 [Lancaster, Pa.].

The author mentions Marfan's description of dolichostenomelia in 1896 and also Archad's emphasis on the spidery extremities, with the term "arachnodactyly," and Boerger's report on the association of dislocated ocular lenses with the arachnodactyly. The hereditary transmission of the abnormalities referred to as Marfan's syndrome has been pointed out, and a number of families, each containing multiple cases of the syndrome, have been described. The S. family is believed to have contained at least 33 affected members in 6 generations. The skeletal, ocular, cardiovascular, and hereditary characteristics of Marfan's syndrome are all well exemplified in this family.

The first generation of the S. family was a young couple who emigrated from Baden in southern Germany to a county in Ontario, Canada, about 1853 or 1854. The diagram of the genealogical tree of the S. family indicates the affected members. The histories of the living patients and of the 17 who have died are presented. The understanding of Marfan's syndrome has been hampered by ignorance of the criteria necessary for its diagnosis. Spidery extremities have been accepted by certain authors as a sufficient condition for this diagnosis, but it has been pointed out that long, slender limbs may also occur in eunuchoidism or as an anthropological variant. Lens dislocation or aortic medionecrosis, as isolated abnormalities, should also not be accepted as pathognomonic of Marfan's syndrome. The complete triad of skeletal, ocular, and aortic abnormalities provides the most substantial basis for the diagnosis of Marfan's syndrome. Study of families confirms that incomplete forms of the syndrome (formes frustes) do occur.

The association of dislocated ocular lenses with brachymorphism is known as the Weill-Marchesani syndrome. The patient with this syndrome is short and has a round head and short, pudgy extremities. Two of the 33 affected members of the S. family are accepted as examples of the Weill-Marchesani syndrome. The author assumes that the morphologic differences between the Weill-Marchesani and the Marfan syndrome do not justify any genetic distinction between the 2 syndromes.

The incidences of the stigmata of Marfan's syndrome in the 17 affected members known to have been examined by physicians or optometrists were: dislocation of ocular lenses, 94%; dolichocephaly, 94%; arachnodactyly, 70%; clinical evidence of aortic disease, 15%. The incidences of these stigmata did not change appreciably from one generation to the next in the medically examined affected members of the 4th, 5th, and 6th generations. Affected male members now dead had a lower fertility rate (average, 0.4 child each) and less capacity to transmit the abnormal gene (average, 0.1 affected child each) than did affected female members (average, 4.7 children each; average, 2.3 affected children each). The average lifespan of 16 deceased affected members was 45 years. Cardiovascular diseases caused the deaths of at least 11 of 17 affected members; aortic disease accounted for at least 3 of the 11 deaths attributed to cardiovascular disease.

These observations support the conclusions that, in the S. family, Marfan's syndrome is transmitted by a single pleiotropic abnormal gene; expression of this gene results in an abiotrophy of the cardiovascular system. Prohibition of childbearing by affected women would be expected to reduce the number of affected persons in succeeding generations.

SURGERY

Open Heart Surgery at the San Juan City Hospital. F. L. Raffucci, J. F. Bernal, M. Blasini and others. Bol. Asoc. méd. Puerto Rico 51:347-353 (Oct.) 1959 (In English) [Santurce].

Three patients with cardiac symptoms were observed at the San Juan (Puerto Rico) City Hospital; the ages of the patients ranged from 16 to 47 years. Diagnosis of an interatrial septal defect was made from the results of clinical, electrocardiographic, and roentgenographic examinations and of cardiac fluoroscopy. Repair of the interatrial septal defect was carried out under direct vision of the defect, with the patient under moderate hypothermia, the temperatures at caval occlusion varying between 27 and 28 C (80.6 and 82.4 F). No complications occurred during the operation in the first and second patients. In the third patient, ventricular fibrillation developed immediately after the closure of the defect. Fibrillation was converted into normal sinus rhythm by application of cardiac massage. The immediate postoperative period was free from complications in the first and third patients. In the second patient, massive atelectasis of the left lung developed on the second day after operation; it did not improve with tracheal aspiration, but was controlled by tracheotomy. There were no deaths in this group. The patients were discharged between 30 and 34 days after operation. A follow-up for one year showed that they were asymptomatic. The authors conclude that moderate hypothermia is the easiest and safest procedure to be used in open-heart surgery for the repair of an interatrial septal defect.

A Clinicopathologic Review of 80 Cases of Struma Lymphomatosa. A. A. Stein. Surg. Gynec. & Obst. 109:544-548 (Nov.) 1959 [Chicago].

A review of 143 cases of diffuse chronic thyroiditis, in which operation was performed at the Albany (N. Y.) Hospital between 1937 and 1953, revealed 80 cases which presented the features of chronic lymphomatous thyroiditis, also known as struma lymphomatosa or Hashimoto's disease. The clinical records and the pathological materials were carefully studied. While the patients ranged in age from 10 to 70 years, the average age was 53.3 years. Only 6 of the 80 patients were men. In more than half of the patients goiter had existed for 5 years or more, and in many of them since childhood. New complaints—either onset of toxicity, glandular enlargement, pressure effects, or hypothyroid features noted in the preceding few weeks or months—induced many of the patients to request medical aid. Initially the thyroid increased in size and weight, but in the late stage it became small and sclerosed.

After subtotal resection, most patients had signs and symptoms of myxedema within a few weeks. These patients needed and received comparatively large doses (1 to 3 grains) of desiccated thyroid daily and showed no sensitivity to thyroid on initiation of therapy. Follow-up examination indicated the need for continuous medication. Except for the relief of pressure symptoms, subtotal resection of these glands, even if the diagnosis is delayed until surgical exploration, seems unnecessary. At the time of surgical exploration, the surgeon can usually make the correct gross diagnosis. Any surgical procedure only hastens the inevitable hypothyroidism. Morphologically, the thyroid was composed of 2 types of epithelial structures, microfollicles and macrofollicles. Each follicular variant had distinct patterns of hyperplasia and involution. The variation in number and functional activity of these 2 epithelial structures created graded differences in morphologic pattern. The variations in clinical features merely reflected the proportion and activity of these 2 structural units.

Experimental Evaluation of Systemic and Coronary Arterial Pressure Response Associated with Ligation of the Internal Mammary and Subclavian Arteries. R. J. Botham, G. G. Rowe and J. W. Gale. Am. Heart J. 58:719-725 (Nov.) 1959 [St. Louis].

The authors discuss data acquired in an experimental evaluation of the systemic and coronary arterial pressure response associated with ligation of the internal mammary arteries in dogs. These studies were undertaken in an attempt to establish whether internal mammary artery ligation is followed by a demonstrable rise in pressure in the proximal segment of the internal mammary artery, whether the associated rise in pressure, if it occurs, is transmitted into branch arteries, and, lastly, whether the rise in pressure is localized to the internal mammary-pericardiophrenic system. Healthy mongrel dogs, weighing 18 to 28 kg. (40 to 62 lb.), were used. Group 1 consisted of 10 dogs in which simultaneous pressure determinations were recorded from the internal mammary, subclavian, and femoral arteries. Pressures were first measured and recorded prior to, during, and subsequent to ligation of the left internal mammary artery. Pressures were then measured and recorded prior to, during, and subsequent to ligation of the left subclavian artery. Group 2 consisted of 5 dogs in which simultaneous pressures were recorded in the subclavian and left anterior descending coronary arteries prior to, during, and subsequent to ligation of the left internal mammary and subclavian arteries. Group 3 consisted of 5 dogs in which extrapleural bilateral internal mammary artery ligations were performed. Direct arterial punctures with no. 20 needles allowed simultaneous intra-arterial pressure determinations from the proximal and distal segments of the ligated arteries at periods of 2, 4, and 5 weeks after ligation of the arteries.

Ligation of the internal mammary artery in dogs was found to cause an associated consistent rise in pressure of a varying magnitude in the proximal segment. The rise in pressure in the proximal segment of the ligated artery was transmitted from the parent vessel to its branch segments. The evoked pressure response, however, was not localized to the internal mammary-pericardiophrenic system but was a simultaneous generalized response recorded in both the systemic and the coronary arterial system. The nature of the pressure response suggested that the generalized rise in the systemic and coronary arterial pressure after ligation of the systemic artery was due in part to neural and/or humoral factors.

Results and Evaluation of Subtotal Adrenalectomy in Patients with Hyperfunction—Cushing's Syndrome: Report on Six Cases. J. M. Bayer. Arch. klin. Chir. 291:531-561 (no. 6) 1959 (In German) [Berlin].

The author reports on a 49-year-old man and 5 women, between the ages of 20 and 43 years, with adrenal cortical hyperfunction (Cushing's syndrome), who were operated on at the surgical clinic of the University in Bonn, Germany. The duration of symptoms before the surgical intervention varied from 2 to 17 years. All the patients had blue-red moon face, buffalo hump, obesity of the trunk, and intumescent abdomen. There were eosinopenia and excretion of large amounts of steroid in the urine. All the patients had hypertension ranging from 130/80 to 230/125 mm. Hg. Two patients had a high degree of osteoporosis. All the patients had a marked tendency to infections. The women had disturbances of the sex cycle, and the man complained of complete loss of libido and of potency. One of the women had a depressive-paranoid psychosis, and 2 other women and the man were apathetic and depressed. The carbohydrate metabolism was disturbed in 4 women and in the man.

Surgical treatment consisted of resection of seven-eighths of the right adrenal gland and of two-thirds of the left adrenal gland in one woman who was the first to be operated on. In the other 5 patients, one adrenal gland was removed completely and four-fifths to seven-eighths of the other adrenal gland was removed. Thus, 90 to 94% of the total gland substance was removed. All operations were performed in 2 stages. The acute risk in the immediate postoperative period and the necessity of long-continued administration of cortisone to combat relative cortical insufficiency, depending on the adaptation to the excessive adrenal cortical hormone, have been emphasized. All 6 patients survived the operations and were followed up for periods ranging from 15 months to 6 years and 3 months. In the woman who was the first to be operated on, an incomplete remission was obtained because of the insufficient adrenal resection; after 15 months this patient's condition became gradually worse, particularly concerning hypertension, although a complete relapse did not occur. The other 5 patients who underwent subtotal adrenalectomy had a complete remission except for the hypertension in 2 patients and except for the osteoporosis. The blood pressure was restored to normal, or considerably improved, in 3 patients. The osteoporosis regressed, but was still notable. There were neither clinical nor biochemical indications of an actual or imminent recurrence. Two of these 5 patients are living without any substitution therapy; intramuscular exogenous corticotropin (ACTH) tests, however, showed that there was no return of function of their adrenal remainders. One patient required a small dose of cortisone daily. The remaining 2 patients had complete adrenal insufficiency; a salt-loss syndrome developed, which required the administration of a mineral corticoid preparation. In one of these patients work capacity was restored by substitution therapy, but within 16 months after the adrenalectomy the first manifestations of a pituitary tumor appeared. In the other 4 patients with subtotal adrenalectomy, the total results were highly satisfactory. Characteristic changes of the skin of the face and of the extremities, such as dryness, itching, and fine-lamellar scaling, occurred early after the operation in these patients, and are to be considered as definite signs of the success of the adrenalectomy. In one patient a preoperative glaucoma subsided after the operation.

The necessity for early diagnosis and early operation in patients with adrenal cortical hyperfunction is emphasized with respect to the insufficient effect on hypertension in the presence of secondary vascular lesions. The advantages and disadvantages of subtotal and total bilateral adrenalectomy are discussed. Franksson's method of autotransplantation of adrenals into the sartorius muscle, combined with total adrenalectomy, deserves a trial on a larger scale. Careful follow-up with respect to the formation of pituitary tumors after total adrenalectomy is imperative.

Primary Repair of Benign Strictures of the Bile Duct. R. B. Cattell and J. W. Braasch. Surg. Gynec. & Obst. 109:531-538 (Nov.) 1959 [Chicago].

From 1919 to May, 1959, 690 patients with benign biliary stricture have been treated at the Lahey Clinic with 1,006 operative procedures. From this series a group of 501 patients, first seen between the years 1940 and 1955 inclusive, has been selected for closer scrutiny, particularly as regards indications for operation and the results of primary stage repair. A total of 447 primary repairs of biliary stricture have been performed in this group of 501 patients, including 207 end-to-end anastomoses of the duct, 142 hepaticojejunostomies, 15 hepaticoduodenostomies, 46 plastic procedures, and 37 dilatations of ductal strictures.

The results 3 or more years after primary repair of biliary stricture are tabulated. The authors believe that strictures are likely to recur after this period of time. Of the patients reporting a satisfactory result 3 years after operation, only 4% subsequently noted return of symptoms of the disorder. The majority of the patients with satisfactory results have experienced no symptoms referable to the biliary tract. The others (5 to 10%) have only infrequent, mild symptoms of obstruction. The postoperative mortality rate ranged from 2 to 5%, and the satisfactory results at the end of 3 years ranged from 43 to 68% after the various methods of repair. The authors regard the end-to-end repair with anastomosis of the 2 ends of the bile duct as the procedure of choice for benign biliary stricture. This procedure should be accomplished over an inlying T tube, the vertical limb of which is brought out either above or below the anastomosis.

Partial Controlled Splenectomy: Preliminary Report on the First Three Cases. M. C. Christo. Hospital 56:645-650 (Oct.) 1959 (In Portuguese) [Rio de Janeiro].

The author presents a surgical technique for "partial controlled splenectomy," developed according to the concept of independent vascular areas in the spleen presented by Zappalá and Neder at the University of Minas Gerais, Brazil. The first 3 patients operated on by this technique were a 40-year-old man with a knife wound, a 6-year-old girl, and a 23-year-old man with a bullet wound. The choice of technique in all 3 cases was dictated by the nature of the wound, a thoracophrenolaparotomy at the left intercostal space being the adequate surgical approach. In each of the 3 patients the spleen had been perforated and bled profusely. The arterial branches in the wounded area were ligated, which caused immediate arrest of the hemorrhage. A dark, shrunken purple area could be seen at the lower splenic end, its aspect contrasting with the rest of the organ. The spleen was resected on both sides of the dark area (approximately 5 cm. on each side), and the whole lesion was removed with an incision perpendicular to the great axis of the organ. There was a mild hemorrhage from arterial branches, which was arrested by ligation. The gastric and pulmonary areas involved were repaired, and the wound was closed in planes. Two patients required pleural drainage.

In each of the 3 patients it was possible to observe the presence of a thin splenic arterial interzonal branch.

The author recommends that after the partial resection the bleeding surface of the remaining spleen be covered with Gelfoam and not with the epiploon. In the resection of intermediate areas the remaining portions may be united by separate stitches in the organ's capsule. The use of partial splenectomy is recommended not only for localized traumatic lesions of the spleen but also for any pathological process limited to a definite splenic "vascular area."

The Emergency Portacaval Shunt. G. E. Wantz and M. A. Payne. Surg. Gynec. & Obst. 109:549-554 (Nov.) 1959 [Chicago].

Whenever possible, the authors have treated bleeding esophagogastric varices by decompressing the portal bed with an end-to-side portacaval shunt as soon as the hemorrhage has been controlled by esophageal tamponade, and the patient's vital signs have been stabilized. They present an analysis of their experiences with this emergency portacaval shunt in 24 patients treated at the New York Hospital–Cornell Medical Center, since 1950. The series included 7 women and 17 men, whose ages ranged from 16 to 70 years and averaged 47.7 years. Fifteen patients had alcoholic cirrhosis, and one of these had a hepatoma. Four patients had postnecrotic cirrhosis, and one of these also had hepatic endophlebitis. Four patients had primary biliary cirrhosis, and in one of these it was associated with hepatoma. There was one patient with a proliferative endophlebitis of the hepatic veins. Both instances of hepatic endophlebitis and both instances of hepatoma went unrecognized until postmortem examination. None of the patients were in hepatic coma at the time of operation.

Three groups of patients were differentiated according to the degree of hepatic damage. Group A patients had mild hepatic disease with a bilirubin content of less than 2 mg. and an albumin content of more than 3.5 Gm. per 100 cc.; they had never been in a coma, and did not exhibit ascites or muscle wasting. Group B patients had moderate hepatic damage when icterus was present, but the bilirubin content was less than 3 mg. and the albumin was usually between 3 and 3.5 Gm. per 100 cc. These patients had never had more than moderate muscle wasting; they had never been in coma, and when ascites was present, it was transient and easily controlled. Group C patients had advanced hepatic disease and jaundice, and their serum albumin level was usually below 3 Gm. per 100 cc. They had frank muscle wasting and had been in coma; ascites generally existed and was difficult to control.

Review of the cases revealed that the over-all condition of the patient, as judged by muscle wasting, coma, and jaundice, constituted the significant prognostic feature, since 6 of 8 patients with marked atrophy of the muscles died and 5 of the 8 patients who had been in a coma before the operation also died. In answer to the question as to why poor-risk patients were subjected to an operation of the magnitude of portacaval shunt, the authors point out that in 11 patients shunts were used because bleeding recurred immediately or within 1 to 3 days upon deflation of the esophageal balloon. The fact that patients with cirrhosis deteriorate with recurrent bleeding led them to attempt early portal decompression in an effort to salvage more of them. Thus far, the authors have performed an end-to-side portacaval shunt on 7 patients without waiting to see if bleeding would recur upon discontinuing pneumatic tamponade, but whereas the 5 patients with mild or moderate cirrhosis recovered, the 2 with advanced cirrhosis died. Of 15 poor-risk patients with demonstrably unrelenting hemorrhage, 6 survived to lead normal lives. Although the operative mortality is bound to be high in these patients, without surgical intervention death seems inevitable.

The authors conclude that portacaval shunt need not be delayed in patients who have been in a steady state of comparatively good health prior to bleeding from esophagogastric varices. However, patients whose health has progressively deteriorated before hemorrhage and in whom the bleeding represents additional evidence of hepatic decompensation should be given a trial of balloon tamponade. Provided that the patient is not moribund or preterminal, portacaval shunt offers the only certain method of controlling massive hemorrhage which continues or recurs despite correct nonoperative treatment. Operation is probably contraindicated in patients with marked jaundice or with a serum bilirubin value exceeding 4 mg. per 100 cc. associated with portal cirrhosis.

The Clinical Behavior and Management of Primary Malignant Lymphoma of the Stomach. G. McNeer and J. W. Berg. Surgery 46:829-840 (Nov.) 1959 [St. Louis].

Thirty-six patients with an apparent primary lesion in the stomach, and with metastases confined to the perigastric area, were observed at the Memorial Center for Cancer and Allied Diseases in New York during 1935-1956. This series represented 2.2% of all malignant tumors of the stomach seen at the center during that period. The practical criterion established in this study for confirmation of the primary character of the tumor was applicability of standard gastrectomy as a therapeutic procedure. There were 22 men and 14 women in this series. Only 3 patients were under 40 years of age; the great majority (24) were in the 50-70 age group. The average duration of symptoms prior to the start of a definitive treatment was 8 months, the longest duration being 3 years, and the shortest 1 day. The commonest clinical picture was suggestive of peptic ulcer. In 9 patients there was an acute loss of weight, which the authors consider characteristic of primary gastric lymphoma. In 2 patients there were palpable abdominal masses.

The 36 patients underwent surgery. Five of them had only laparotomy because of the advanced stage of their disease. In one patient, whose massive lesion of the cardia had been diagnosed as lymphosarcoma on biopsy, the tumor resolved completely under x-ray therapy, and the man was still free from disease 19 years later. Seventeen patients underwent subtotal gastrectomy, and 14 total gastrectomy. Postoperative radiation was administered unsystematically, either with the radio cobalt unit or x-ray voltages of one million or more to give the tumor a dose of 3,000 to 4,000 r. There were 1 operative and 3 postoperative deaths; 5 patients died within 3 years. Twenty patients were followed up in a 5-year survey. There were 7 survivors, 5 of whom had received the combined gastrectomy-radiation treatment. Histologically, 3 types of tumor were distinguished—purely lymphocytic tumor, reticulum-cell tumor, and an intermediate group. At a 3-year follow-up the survivors were 4 patients with lymphocytic tumor, 2 of 8 patients with the intermediate type, and 3 of 6 with reticulum-cell lymphoma. The authors conclude that radical surgery plus radiation therapy is the most effective form of treatment, and that the only clinically significant separation of the operable lymphomas by cell type lies in the segregation of the purely lymphocytic lymphoma from the tumors with any less differentiated components.

Cancer in Ulcerative Colitis. G. Slaney and B. N. Brooke. Lancet 2:694-698 (Oct. 31) 1959 [London].

In the past decade the development of surgical methods in the treatment of ulcerative colitis has brought increasing awareness of the problem of carcinomatous change. Reports from the literature indicate that cancer of the large intestine is much commoner in patients with ulcerative colitis than in persons without it. The incidence of cancer in medically treated patients with ulcerative colitis has been found to be between 3 and 4%, and in surgically treated patients to be twice as high; it has been known to reach 30% when ulcerative colitis had been present for 10 years or more.

Data are presented on 18 patients in whom carcinoma arose subsequent to ulcerative colitis. Fifteen of the 18 patients belonged to a series of 222 patients with ulcerative colitis, who had been referred to the authors for surgical treatment. The over-all incidence of carcinomatous change was 6.7%, and rose to 17% in those with ulcerative colitis of 10 or more years' duration. An analysis of this and other series suggests that the 5-year survival rate in cases of carcinoma complicating ulcerative colitis is no higher than 18.6%. The average age at which carcinoma develops is 42 years in those with ulcerative colitis, compared with 63 years in previously healthy persons. Carcinoma may develop after a quiescent or healing phase. The lesion can be difficult to detect clinically, radiologically, and on naked-eye inspection of the intestine after removal. Simple deflection of the fecal stream by ileostomy does not protect the intestine from malignant change, which can arise both in retained and in defunctioned large intestine and in a functioning rectum after ileoproctostomy.

Interruption of the Pituitary Stalk in the Patient with Mammary Cancer. G. Ehni and N. E. Eckles. J. Neurosurg. 16:628-652 (Nov.) 1959 [Chicago].

The authors report on 17 women, between the ages of 26 and 58 years, with metastasized cancer of the breast, who were subjected to section of the pituitary stalk, followed by implantation of a mechanical barrier to regeneration of the hypophysial portal vessels, at the Anderson Hospital in Houston, Texas. There were 2 operative deaths. The other patients survived for periods ranging from 2 to 22 months. Interruption of the pituitary stalk produced regression of the widespread breast cancer in 5 patients who showed improvement by gain in weight, improved erythropoiesis, diminished calcium excretion, roentgenographically observable osteoblastic change, and, in some instances, resumption of normal trabecular pattern in bone lesions. In 4 of these 5 patients lactation was discovered 1 to 10 months after the operation. Lactogenic hormone, seemingly elaborated by the surviving pars distalis, unaided by ovaries or adrenals, produced and maintained lactation in these patients. It is believed that impairment of secretion of the milk-ejection factor deriving from the posterior lobe accounted for failure of lactating women to become aware of lactation spontaneously.

Laboratory findings during the postoperative survival period revealed that the output of adrenocorticotropic hormone was greatly depressed after interruption of the stalk. The thyroid-stimulating function of the pituitary gland was greatly reduced in most of the patients, but this reduction seems not to be as invariable or as immediate as it has been reported to be after efficient hypophysectomy. The anti-insulin effect of the normally functioning anterior lobe was reduced strikingly in some patients but was reduced only moderately in others. Division of the pituitary stalk produced polyuria in all but one surviving patient. It did not appear that this development was conditional on persisting function of the anterior lobe or on substitution therapy given for deficiency of the anterior lobe. Judging from the effects on menstruation and on the ovaries, uterus, and vagina of one long-term survivor, interruption of the stalk abolishes gonadal-stimulating and genital-stimulating activity of the pituitary gland.

Autopsy findings revealed that section of the pituitary stalk produced infarction in the anterior lobe of the pituitary, which corresponded with the pattern of infarction in the medial portion of the pars distalis with extensions laterally, which had been observed by other workers in rats. Histological examination of the viable-appearing cells by a variety of techniques, calculated to reveal specific losses of cells or cytological abnormalities, failed to show them, and no difference is believed to exist between the parts of the anterior lobe which survived interruption of the stalk and the normal. The cells that survive may amount to one-fourth of the preoperative volume of the anterior lobe. The isolated surviving cells of the anterior lobe probably behave in a fashion identical with pituitary isografts.

The reported data showed the authors' hypothesis, which maintained that interruption of the pituitary stalk is the physiological equivalent of total hypophysectomy, to be invalid. While the effects on the gonads and the adrenals seem substantially the same, the effects on the thyroid and on carbohydrate metabolism may be milder or less consistent. The greatest difference between the 2 interferences with function of the anterior lobe lies in the lactational effect of interruption of the stalk. Though the authors' experience shows a positive association between lactation and regression of the tumor, it cannot be asserted that lactation so produced is of benefit in breast cancer. Though this series is too small to support a conclusion comparing the efficacy of interruption of the stalk with hypophysectomy in the treatment of breast cancer, the anticancer effects of the two appear to be similar. The observed association between lactation and regression of the tumor deserves further study.

Hepatic Artery Aneurysm: Report of a Case Treated by Excision. J. G. Jontz. Surgery 46:896-901 (Nov.) 1959 [St. Louis].

The author reports a case, which he believes to be the 6th, of total excision of an aneurysm of the hepatic artery. The patient, a 67-year-old man, was hospitalized at the Medical Center of Indiana University, in Indianapolis, because of a pulsating mass in his lower abdomen which had been present for 5 years. This mass had been increasing in size, and the patient had been suffering from epigastric discomfort which seemed to be aggravated by the ingestion of fatty foods. Physical examination showed a blood pressure of 190/90, pulsus alternans, and a grade 2 systolic murmur at the apex. There was a mass, about 5 by 10 cm., in the middle of the lower abdomen, tender to palpation, with intrinsic pulsation and a systolic bruit. The electrocardiogram showed a complete left bundle-branch block, premature atrial beats from different foci, and short runs of tachycardia. The roentgenologic examination revealed calcium in an abdominal aortic aneurysm and in what was interpreted as a possible splenic artery aneurysm.

The patient was placed on digitalis therapy, and his cardiac rhythm difficulties improved. At operation, an abdominal aortic aneurysm was found, measuring 4 by 4 by 6 cm. This aneurysm was excised, and a straight, stretch-weave Dacron graft was interpolated between the transected ends of the aorta. An aneurysm of the hepatic artery arose from the common hepatic artery and ended at the gastroduodenal branch. The hepatic artery was occluded proximally and distally with noncrushing vascular clamps, while the gastroduodenal, right gastric, right and left hepatic arteries maintained pulsatile blood flow. The aneurysm was excised, and the transected ends of the hepatic artery were sutured with a 5-0 arterial suture. Antibiotic postoperative therapy was instituted. The patient made an uneventful recovery and remained in good health 9 months after his discharge from the hospital.

A 26 Year Experience in the Surgical Treatment of 5,037 Patients with Nonmalignant Biliary Tract Disease. F. Glenn. Surg. Gynec. & Obst. 109:591-606 (Nov.) 1959 [Chicago].

Since 1932 a careful account has been kept of patients with biliary tract disease, who have been cared for in the surgical pavilions of the New York Hospital-Cornell Medical Center. During this period detailed records have been maintained and frequently reviewed. Concomitantly, numerous studies upon selected groups of patients have been made. By 1958 a 26-year period had elapsed, during which 5,037 patients had been treated surgically for nonmalignant biliary tract disease. The author has reviewed clinical experiences in conjunction with follow-up evaluation of patients who have been observed for long periods. He has also investigated the present policies and practices in the management of patients with biliary tract disease.

The author found that there has been a wider acceptance of surgical therapy for this malady. Contributing to this trend has been a reduction in the morbidity of complications and in the mortality rate. Surgery is accomplished with greater ease as well as with increased safety. It is contended that this trend will continue as the time interval between the establishment of diagnosis and operation is further reduced. Evaluation of patients with anticipation of possible complications, resulting in better preoperative preparation and meticulous attention to the technical steps involved, should improve the results in the future. The difference in the mortality rate of 0.5% for 2,712 patients under 50 years of age and 3.2% for 2,325 patients 50 years of age and older, treated surgically for nonmalignant disease of the biliary tract, emphasizes the importance of early diagnosis and early operation.

Experience with Hypophysectomy in Inoperable Cancer of the Breast. E. Pardal, A. Belou and A. R. Walder. Prensa méd. argent. 46:1041-1045 (April 24) 1959 (In Spanish) [Buenos Aires].

Ten women, between 49 and 75 years of age, with metastasized cancer of the breast, underwent hypophysectomy as a palliative treatment. All 10 patients had been operated on before, 9 having undergone mastectomy and one being subjected to resection of the mammary nodule. The hypophysectomy was performed through a transseptosphenoidal approach and by curettage. Premedication consisted of 100 mg. of cortisone given every 12 hours over a period of 48 hours immediately preceding the operation. The postoperative period was complicated in one patient by diabetes insipidus, which developed in consequence of the high resection of the hypophysial stem; in another patient there developed a fistula discharging cerebrospinal fluid, which subsequently led to meningitis and death.

All 10 patients experienced relief from pain and a satisfactory hormonal balance immediately after the hypophysectomy. In only one patient was this relief temporary. Seven patients were living at the time this article was written. The survival rate varied from 2 to 11 months. Six of the surviving patients were in good general condition and free from symptoms. The 7th survivor was the patient who suffered a relapse of pain. The authors believe that the effects of hypophysectomy are manifest within a few hours after the operation, bringing about a feeling of well-being and relief from the symptoms. In the great majority of patients the tumors decrease in size, the local trophism is improved, the osseous metastases are calcified, and the pathological fractures are consolidated.

Elective Cardiac Arrest by Anoxia During Extracorporeal Circulation. G. Dubourg, F. Fontan, D. Cottin and others. Semaine hôp. Paris 35:3081-3085 (Nov. 18) 1959 (In French) [Paris].

The authors performed a series of experimental studies on dogs in order to compare in open-heart surgery 2 methods of elective cardiac arrest, that is, by the injection of potassium citrate and by anoxia during extracorporeal circulation. The latter method offered by its innocuousness, its effectiveness, and the simplicity of its technique considerable advantages over elective cardiac arrest by potassium citrate. Complete cardiac arrest was less rapidly induced by anoxia than by the injection of potassium citrate, requiring from 8 to 10 minutes; this delay, however, proved to be an advantage because it enabled the surgeon to operate on a completely dry and flaccid heart. Elective cardiac arrest by anoxia was used during open cardiotomy in 15 patients with various heart diseases, their ages ranging from 5 to 30 years. The heart-lung apparatus of Senning was used in all the patients. Of the 15 patients, 12 were cured; the 3 deaths could not be ascribed to the effect of anoxia. The greatest advantage of this method lies in the fact that the conductive bundles can be controlled at will and the arrest of coronary circulation can be repeated as many times as necessary, whereas the injection of potassium citrate cannot be given repeatedly. After removal of the clamps, normal heart rhythm was resumed much more rapidly than after cardiac arrest by potassium citrate. The authors emphasize that, in their opinion, cardiac arrest by anoxia is the method of choice in open operations for the correction of congenital heart disease.

Embolectomy in Protracted Fatal Pulmonary Embolism. R. Nissen. Schweiz. med. Wchnschr. 89:1169-1172 (Nov. 7) 1959 (In German) [Basel, Switzerland].

Of the 19 patients with pulmonary embolism whose lives were saved by embolectomy, 11 were operated on during the 16 years between 1924 and 1940, and only 8 during the last 18 years from 1941 to 1959. In view of the decisive advancement in cardiovascular surgery during the recent years, the author feels that this decrease in the performance of Trendelenburg's embolectomy is somewhat surprising, the more so since some of the advances in cardiovascular surgery might prove helpful in the Trendelenburg embolectomy. He points out that the majority of massive pulmonary embolisms are immediately fatal and that it is inadvisable to perform embolectomy practically after death, in the hope that cardiac massage will revive the patient, for although heart action may be restored, the brain will have suffered irreparable damage. For these reasons embolectomy should be attempted only in those whose heart is still functioning after all preparations for the operation have been completed, including exposure of the pulmonary artery. Even in hospitals that are fully equipped for emergency embolectomy, from 15 to 30 minutes will be necessary for preparation. It will be found that in many patients immediate embolectomy will no longer be necessary, because there has been spontaneous recovery from the embolism.

At the author's clinic it is the practice to prepare for embolectomy patients in whom the symptomatology indicates massive pulmonary embolism, and to have the surgical staff and sterile instrumentarium in readiness, while the patient's blood pressure, respiration, degree of dyspnea, and inflow stasis are kept under constant watch. The data obtained in this manner are just as informative as continuous electrocardiographic recordings. Under such conditions, the author performed the Trendelenburg embolectomy on 2 patients with what has been designated "slowly fatal acute cor pulmonale." He reports on a 73-year-old woman on whom a successful embolectomy was performed 24 hours after the first signs of embolism. The 24-hour delay makes the case noteworthy, since among the 19 successful operations for pulmonary embolism recorded in the literature there were only 2 others with similar intervals between onset and operation, 18 hours in one case and 40 in the other.

The Management of the Ruptured Aortic Aneurysm. J. Storer and R. C. Smith. A. M. A. Arch. Surg. 79:711-714 (Nov.) 1959 [Chicago].

Aneurysm of the abdominal aorta can be detected by palpation. When the patient is lying on his back, a pulsating mass can be felt even in the obese patient. A high index of suspicion on the part of the surgeon is important. Backache is an important symptom, and many aneurysms are detected by radiologists during "back studies." Aneurysms usually rupture within a few years. Since the aorta is retroperitoneal, the ruptured aneurysm may be contained by the peritoneum for a time, but when the enlarging hematoma ruptures the peritoneum, death threatens. The initial abdominal pain may be so intense as to cause syncope. Irritation of the sigmoid colon frequently causes diarrhea. The blood may dissect along the retroperitoneal tissues and present in the inguinal canals, leading to a mistaken diagnosis of incarcerated inguinal hernia.

As soon as the diagnosis is made, a blood count, urinalysis, blood typing, and cross matching are the only laboratory procedures requested. The patient is taken to the operating room immediately. Two "cut-downs" are done, and blood transfusion is started. In their first operations for ruptured aneurysms, the authors paid little attention to the anesthetic management, but now they use neuromuscular blocking agents prior to induction of anesthesia. The patient is completely paralyzed by succinylcholine (Anectine) chloride. Endotracheal intubation is then accomplished, and the patient is anesthetized.

The abdomen and left chest are draped, and a lower left rectus incision is made. A submammary incision is made in the left side of the chest. The pleura is entered, the aorta is isolated just above the diaphragm and a Satinsky clamp placed around it, but its jaws are not closed. The abdominal incision is then lengthened to the pubis, the viscera packed off, and dissection begun. The aorta is isolated above the aneurysm, which is usually below the renal arteries. In what the authors refer to as the "friendly space," where the vena cava and the aorta are usually not adherent, blunt dissection with the index finger will enable the surgeon to encircle the vessel in a few minutes. The Satinsky clamp is removed from the thoracic aorta and placed across the abdominal aorta at the point of dissection. Again, the jaws are left open. Removal of the aneurysm is carried out, and aortic continuity is reestablished by the insertion of a preclotted elasticized Dacron graft. The jaws of the Satinsky clamp are closed only if bleeding seriously interferes with manipulation.

The authors have seen no serious impairment of renal or hepatic function by clamping the aorta for 10 minutes. They describe 3 illustrating case histories. They conclude that excision and grafting are the ideal treatment of an arteriosclerotic aneurysm of the abdominal aorta. The aneurysm should be thought of as a malignant lesion. One should not postpone surgery any more than if one were dealing with a carcinoma of the large intestine. The diagnosis of aortic aneurysm must be considered in the presence of the signs of the "acute abdomen" in patients past the 4th decade.

The Surgical Management of Functional Adrenal Hypercorticism. R. C. Overton, J. W. Overstreet and R. V. Ford. A. M. A. Arch. Surg. 79:791-798 (Nov.) 1959 [Chicago].

The improvement of laboratory techniques for diagnosis of abnormal adrenal states has made it possible to detect patients in an earlier phase of hyperadrenocorticism than that which is usually referred to as Cushing's syndrome. The authors present observations on 16 of these patients who were subjected to total bilateral adrenalectomy. They believe that hyperadrenocorticism is initially a cyclical disease, which is generally progressive. Since there is no chemotherapeutic agent that will inhibit hypercorticism (without prohibitive toxicity), the authors regard total adrenalectomy as not too drastic a procedure in view of the prognosis of untreated hypercorticism. All except 1 of the 16 patients were women of an average age of 35 years (range from 18 to 53 years). Age greater than 55 years and renal impairment, indicated by a blood urea nitrogen concentration of greater than 30 mg. per 100 cc., were accepted as contraindications to surgical removal of the adrenals. Congestive heart failure, however, was not considered as a contraindication, since 3 of 16 patients were bedridden from cardiac failure for one year or more prior to adrenalectomy.

No preoperative priming with supplemental steroid is instituted, but at the beginning of the procedure, through a separate intravenous infusion, administration of 100 mg. of hydrocortisone, in 1,000 cc. of 5% dextrose in isotonic sodium chloride solution, is started at a slow rate. After both adrenals have been removed, the patient usually receives approximately 30 to 40 mg. of hydrocortisone. Repeated observations of vital signs and hourly urinary output provide the indexes for supportive medications and immediate postoperative management. Vasopressor agents are not necessary. In spite of the ablation of the adrenal medulla, these patients maintain an adequate blood pressure if hydrocortisone and moderate amounts of salt are administered. During the first 24 hours the average hydrocortisone requirement has been 200 mg. administered intravenously by constant slow infusion. Occasionally, more than 9 Gm. of sodium chloride is necessary, particularly if the patient has been on a diuretic regimen. On the first postoperative day intravenous administration of hydrocortisone is continued in a decreased amount, and by the second postoperative day it is supplemented by orally administered hydrocortisone. With the transabdominal approach the patients have much less ileus than with the flank or retroperitoneal approach, permitting the rapid resumption of oral feedings and medication. The orally administered doses of hydrocortisone can be reduced rapidly to from 30 to 40 mg. daily in divided doses.

In spite of the fact that many of the 16 patients had serious hypertensive cardiovascular problems before operation, there were no deaths. The patients have since been followed for from 3 to 18 months, and it is evident that they have been benefited. They were treated at a stage in which their disease might be considered to be functional and not a fully developed Cushing's syndrome.

Glomus Tumor of the Leg: A Case Report. W. E. Hess. Rocky Mountain M. J. 56:51-52 (Nov.) 1959 [Denver].

Glomus tumor, also masquerading under such names as angiosarcoma, perithelioma, painful subcutaneous nodule, glomangioma, sugungual tumor, hemangiopericytoma, and angioneuromyoma, is a relatively rare condition even when found in its usual subungual location. The patient presented was a 52-year-old painter who complained of pain in the left knee of over one year's duration. He described the pain as stinging and burning and stated that even slight bumps and pressure of bed covers aggravated it. He had given up his job as a painter because bumping his knee on the rung of a ladder caused severe pain. The patient's history revealed that he had undergone excision of a torn medial meniscus in the same knee in 1929, following a twisting injury one year previously. Now there was a palpable, slightly mounded area over the anteromedial proximal tibial region on the left, about the size of a 50-cent piece. This area was exquisitely tender to pressure with the tip of a lead pencil directly over the center of the enlargement. The tenderness seemed to be in the skin, since raising the skin and displacing it to one side revealed no deep tenderness. There was a very slight bluish stain, visible only in bright light. Roentgenologic examination revealed a small spur on the patella. The clinical impression was possible glomus tumor. The lesion was excised.

The pathological specimen consisted of an elliptical wedge of skin. Subcutaneously, in the central portion of this wedge of skin, there was a small pink mass of tissue, 3 mm. in diameter. Microscopic examination revealed a well-circumscribed glomangioma. There was no evidence of malignancy. The patient had an uneventful convalescence; he is now free from pain and has been able to resume his work as a painter. The author's search of the literature revealed few reports on glomus tumors in the region of the knee joint.

Treatment of Malignant Pelvic Tumors by Extracorporeal Perfusion with Chemotherapeutic Agents. W. G. Austen, A. P. Monaco, G. S. Richardson and others. New England J. Med. 261:1037-1045 (Nov. 19) 1959 [Boston].

The toxicity of nitrogen mustards and allied compounds to the normal tissues of the gastrointestinal tract and of the hematopoietic system has limited their systemic administration. Direct intra-arterial administration of nitrogen mustard produces high local tumorocidal levels but does not entirely eliminate systemic toxicity. By isolating the circulation of a region bearing a tumor and perfusing it by a method utilizing an extracorporeal circuit, Creech and his associates achieved the twofold advantage of minimizing systemic toxicity and bringing high levels of alkylating agent to the tumor. An oxygenator was incorporated into the perfusion circuit because radiomimetic drugs are presumably more effective with high tissue oxygen tensions. In another communication, the application of regional perfusion of the lower extremity is described, while this paper is concerned with perfusion of the pelvis.

Vascular isolation of the pelvis is achieved by occlusion of the aorta and vena cava by suitable noncrushing vascular clamps and of the femoral vessels in both lower extremities by pneumatic cuffs inflated around the upper thighs. The technique of pelvic perfusion is described, and illustrative case histories are presented. Regression was achieved in 4 of 7 patients with pelvic cancer. Perfusing the pelvis with the patient's own blood, maintained at physiological temperature and pH, will avoid peritoneal reactions associated with the use of bank blood. The importance of monitoring pelvic perfusion pressure and systemic pressure is emphasized. Maintenance of the perfusion pressure at a lower level than the systemic pressure minimizes the loss of drug to the general circulation. The extent of mixing of the perfusate with the general circulation in pelvic perfusion is variable and not accurately predictable. Monitoring the rate of mixing of the 2 circulations during perfusion affords the best means of administering the maximal amount of agent with the minimal risk of systemic toxicity.

In the usual pelvic perfusion, the rate of mixing is approximately 1.5% per minute. Under such circumstances high doses of nitrogen mustard (1.0 mg. per kilogram of body weight) may be given safely. Obstruction of pelvic veins by tumor results in increased collateral blood flow. This is associated with a mixing rate of approximately 3% per minute and requires reduction of the dosage of nitrogen mustard to 0.8 mg. per kilogram of body weight. When occlusion of the major vessels is not complete or cannot be attempted, the drug is lost to the general circulation at a rate of approximately 4% per minute, and the permissible dose is 0.4 to 0.5 mg. per kilogram of body weight. Systemic toxicity is also dependent upon the duration of action of the drug. With the same rate of loss of perfusate to the general circulation, a short-acting drug is better tolerated than a longer-acting agent.

The employment of combinations of drugs with similar effects on tumors and different systemic toxicities may produce more damage to the tumor without increasing the hazard to the patient. It is possible that pelvic perfusion with nitrogen mustard compounds can be combined with radiation therapy for increased effectiveness. Perfusion with chemotherapeutic agents is particularly applicable to pelvic cancer, since tumors of this area frequently cause morbidity and mortality by local encroachment rather than by distant metastases. Control of local disease may result in prolonged survival.

Treatment of Kaposi's Sarcoma of the Lower Extremity by Extracorporeal Perfusion with Chemotherapeutic Agents. A. P. Monaco and W. G. Austen. New England J. Med. 261:1045-1052 (Nov. 19) 1959 [Boston].

Kaposi's sarcoma, or idiopathic multiple hemorrhagic sarcoma, is progressive, and it exhibits a wide range of clinical and histological variations. The initial lesion is most often found on the hands and feet, and it takes the form of a reddened, well-demarcated, insensitive macule that slowly increases in size. Histologically, the appearance is one of inflammation with dilatation of dermal vessels and round-cell infiltration. As the early macule enlarges and becomes elevated, the color darkens to bluish red with hemangiomatous characteristics. Microscopically, the features of a granulomatous reaction are apparent, for edema, hemorrhage, and connective-tissue proliferation are present. A widely accepted view is that the disease is a benign angiomatosis, arising from embryonal vascular cells at multicentric foci. Others belive that it is a true sarcoma and that secondary lesions are metastatic. A third concept holds that Kaposi's sarcoma is a disease of the reticuloendothelial system related to the lymphoma group, and its simultaneous occurrence in patients with Hodgkin's disease and related disorders supports this theory.

The authors discuss the therapy of Kaposi's sarcoma of the lower extremity on the basis of the histories of 2 patients in whom they employed regional perfusion with nitrogen mustard by means of extracorporeal circulation. They describe several types of lower extremity perfusion in which vascular isolation is complete enough, so that the limiting factor to the permissible dose of the chemotherapeutic agent is the tolerance of normal local tissue rather than systemic toxicity. In the adductor-canal perfusion 0.6 mg. per kilogram of body weight is employed, whereas 0.8 to 1.0 mg. per kilogram of body weight is well tolerated in the common femoral and external iliac perfusion. Extremes of perfusion pressure and flow must be avoided, and the patient's own blood, maintained at physiological temperature and pH, must be used to minimize limb edema and tissue swelling.

The case of the first patient, a 79-year-old man, illustrates 2 important aspects of Kaposi's sarcoma: the poor prognosis for a continued remission with radiation therapy once multiple tumors appear in the swollen, edematous extremity, and the complications of radiation therapy in the form of skin breakdown and indolent ulceration. Dye studies revealed essentially total isolation of the perfused extremity with only a 2% loss in 40 minutes and no evidence of systemic toxicity. Perfusion therapy achieved a gratifying and rapid remission in this patient without skin breakdown or other local sequelae. In the second patient, a 65-year-old man, perfusion therapy likewise achieved a gratifying and rapid remission without untoward sequelae. Both of these patients had previously received maximal tolerable doses of local roentgen irradiation. The authors suggest that the perfusion technique may permit previously heavily irradiated tissue to receive effective doses of nitrogen mustard and other radiomimetic agents without dangerous ill-effects.

The Prevention of Primary Postoperative Thrombosis: A Reliable Capillary Tube Clotting Time Method. H. F. McNickle. A. M. A. Arch. Surg. 79:775-784 (Nov.) 1959 [Chicago].

The author performed many hundreds of capillary tube clotting time estimations, for which homemade glass capillary tubes were used. Gradually, by trial and error, he found ways to eliminate some of the variables in the test. Unexpectedly, one of the most important variables was found to be in the capillary tubes themselves. This led to a study of the behavior of homemade capillary tubes when used to test the clotting time of normal blood at body temperature, and to the observation that freshly drawn capillary tubes give short and erratic clotting times, but that tubes from the same batch, after being allowed to age for some months, give very uniform and dependable clotting times, and continue to do so indefinitely. The next step was to use these reliable capillary tubes on patients undergoing major surgery in an effort to predict and forestall primary postoperative thrombosis and embolism. Such an investigation was begun in 1948 and is still continuing.

All batches of tubes were allowed to age naturally until they gave a clotting time of 7 minutes or longer when used on normal patients. The minimum aging time was at least 9 months when tubes were stored in a clear glass box standing on the desk in diffuse daylight. If the tubes remained on the desk after this, the aging process still continued but at a very reduced rate. The author found the capillary tube method reliable and feels that the failure of others to produce comparable results probably lies less in errors of technique than in a failure to appreciate the importance of aging the capillary tubes. It is a mistake to assume that all capillary tubes are identical in their effect on blood coagulation. The following are some advantages of the capillary tube test: 1. The capillary tube is a self-filling expendable container which holds a small sample of blood virtually out of contact with the air. 2. The tubes are clean, since a fresh one has to be used for each test. 3. No venipuncture is required. 4. The equipment is simple, and the test can be done quickly anywhere.

Postoperative clotting time estimations were planned to sort out those patients whose clotting mechanism became unstable in the early postoperative period. It was felt that, if the clotting mechanism had not been upset by the middle of the first week after operation, it was unlikely to become unstable thereafter, unless there were some complicating factor, such as dehydration, sepsis, or an intercurrent infection. Accordingly, the clotting time was studied routinely on the second and again on the third postoperative day. The test was made on 635 patients subjected to major surgery. Prophylactic anticoagulant treatment was given when the postoperative clotting time fell to half, or close to half, of the normal figure, as it did in 8 out of a total of 635 patients (1.3%). Heparin was the only anticoagulant used. It was given in frequent small doses by the subcutaneous route. The duration of treatment (from 2 to 10 days in this series; average, 5 days) was governed entirely by the duration of the patient's heparin resistance or tolerance. There has been no case, or suspicion of a case, of primary postoperative thrombosis since this investigation began 10 years ago.

NEUROLOGY & PSYCHIATRY

The Results of Injecting Hot Water into the Gasserian Ganglion for the Relief of Tic Douloureux.

R. Jaeger. J. Neurosurg. 16:655-663 (Nov.) 1959 [Chicago].

The author reports on 185 patients with paroxysmal trigeminal neuralgia (tic douloureux), who were treated by injecting hot water into the gasserian ganglion at the Jefferson Medical College Hospital in Philadelphia between 1953 and 1958. Relief from the paroxysmal tic pain has been complete in all but 7 patients. Five of these were among the first 30 patients, and they were relieved by operation. It is probable that at least 3 of these, if not all of them, could now be relieved by injection. There has been no operation for relief of the pain in the last 155 patients treated by injection Paralysis of the motor nerve to the muscles of mastication occurred in most, but not all, of the patients; complete regeneration of the motor nerve occurred within 3 or 4 months. There occurred suspected or slight temporary irritation of the cornea. Permanent slightly diminished vision was caused by clouding of the cornea in 2 patients. Slight paresis of the extraocular nerves occurred in 8 patients, but complete recovery always occurred in less than 5 months. Herpes occurred in more than 50% of the patients, usually on the labial mucosa at the corner of the mouth. It appeared 3 days after the injection and disappeared within 3 weeks. Some patients of advanced age or with an anxious, tense personality complained of numbness, stiffness, itching, burning, and crawling sensations over the anesthetized area. Injection of hot water into the gasserian ganglion has accomplished everything that the subtemporal or posterior fossa surgical approaches to the gasserian ganglion or its roots have, and without mortality, facial paralysis, and other complications common to major intracranial operation for tic douloureux.

A Follow-up of Head-Injured Men of World War II.

A. E. Walker and S. Jablon. J. Neurosurg. 16:600-610 (Nov.) 1959 [Chicago].

The authors report on 739 men who had sustained head injuries in World War II and who were followed up in 4 neurological centers in Baltimore, New York, Boston, and Long Beach, Calif., 6 to 9 years after injury. Mental disturbances in the form of impaired judgment, mentation, memory, and alterations in personality could be correlated with all factors related to severity of injury, but not with location of injury. Aphasia was present predominantly when the lesion in right-handed patients was in the left hemisphere, although 21% of such patients had major wounding on the right side. However, among the 47 left-handed patients who sustained head wounds, aphasia was associated only with left-sided lesions. Disturbances of the motor and sensory systems, commonly associated, tended to improve. Headache, usually associated with other post-traumatic symptoms, present in 82% of the men, did not correlate with the severity of injury, but bore a much closer relationship to the "neurotic" type of personality and subnormal intelligence. Some form of paroxysmal epileptic disorder occurred in 28% of the patients in this series, but only 22.9% had more than one definite attack. There was a distinct tendency for the prognosis to be favorable in those patients who had their attacks soon after injury. In the social and economic rehabilitation of the head-injured patient the severity of injury played an important role, but perhaps even more important was the intelligence of the head-injured men.

Seven patients with post-traumatic epilepsy were divided into those who have had no attacks for 2 years or more and those continuing to have attacks. Although the numbers are small, there is no evidence that the brain waves are more often abnormal in the group with seizures than in the seizure-free group. These findings suggest that the encephalogram has a limited value in the prognosis of post-traumatic epilepsy. The reported data suggest that the end-results of head injury in terms of social, economic, and neurological rehabilitation seem to be dependent not only on the severity of wounding but also on the quality of brain that was damaged.

Parkinsonism Due to Midbrain Compression. L. Oliver. Lancet 2:817-819 (Nov. 14) 1959 [London].

The association of parkinsonian symptoms with brain tumors has been mentioned rarely, but in Oliver's experience parkinsonism is not uncommonly associated with intracranial space-occupying lesions, although its physical manifestations are usually overshadowed. He presents the histories of 3 patients in whom parkinsonian tremor and rigidity were associated with intracranial tumors.

In the first patient, edema of the left cerebral hemisphere was diagnosed because of the onset, 7 days after removal of a left-sided meningioma, of drowsiness, motor dysphasia, papilledema, and return of paresis of the right arm. Midbrain compression was indicated by the positive Hoffman and Babinski signs on the left (ipsilateral) side. The right-sided parkinsonian signs were associated, therefore, with edema of the left cerebral hemisphere and the consequent midbrain compression, and they disappeared as the edema subsided. In the second patient, cerebellar edema developed 2 days after operation, and compression of the brainstem was rapid and severe because the dura mater had been sutured. The tremor and cogwheel and lead-pipe rigidity were probably caused by compression of the midbrain at the level of the tentorial opening, arising from upward herniation of an acutely swollen left cerebellar hemisphere. The third patient had no parkinsonian tremor or rigidity, either before the onset of symptoms due to the tumor or when the manifestations of the tumor were confined to the contralateral side. Ipsilateral tremor and rigidity developed when the level of consciousness declined, the ipsilateral tendon reflexes became brisker than those on the right, and the left plantar reflex became equivocal. One cannot argue that the tremor and rigidity were due to an effect on the globus pallidus, because they were ipsilateral.

Midbrain compression is the factor common to all 3 cases, and is the most likely explanation of the development of parkinsonian manifestations in association with some intracranial tumors. This would conform with current views on the site of the pathological process in both idiopathic and postencephalitic parkinsonism, and it is supported by the effects of lesions produced experimentally in the midbrain of monkeys.

Cardiopulmonary Insufficiency in Myotonic and Progressive Muscular Dystrophy. K. H. Kilburn, J. T. Eagan, H. O. Sieker and A. Heyman. New England J. Med. 261:1089-1096 (Nov. 26) 1959 [Boston].

The authors report on 8 men and 1 woman, between the ages of 22 and 58 years, with myotonic dystrophy, and on 6 men and 2 women, between the ages of 22 and 64 years, with slowly progressive nonmyotonic muscular dystrophy, who were admitted to the neurology service at Duke Hospital and the Veterans Administration Hospital in Durham, N. C. Cardiopulmonary function was assessed in these 17 patients. Twelve patients had dyspnea or other respiratory symptoms. The total lung capacity was reduced in all patients, largely by loss of inspiratory reserve volume. The vital capacity and maximum breathing capacity were impaired to a greater degree in the nonmyotonic patients. The patients with myotonia, on the other hand, showed a reduction in minute ventilation, carbon dioxide retention, and a decrease in ventilatory response to carbon dioxide inhalation. Pulmonary hypertension and a reduced arterial-blood oxygen saturation were also observed in some of the myotonic patients. Oxygen inhalation resulted in further reduction in respiratory minute volume and an increase in carbon dioxide tension in 3 of the 8 patients with myotonia, changes that were not observed in those with nonmyotonic dystrophy. These observations indicate that the syndrome of alveolar hypoventilation may appear in patients with myotonic dystrophy, as it does in those with a variety of other clinical disorders, and is probably the result of weakness of the chest bellows, increased work of breathing due to myotonia, and a disturbance in central respiratory mechanisms.

Carotid Artery Occlusive Syndrome. L. J. Hurwitz, S. N. Groch, I. S. Wright and F. H. McDowell. A. M. A. Arch. Neurol. 1:491-501 (Nov.) 1959 [Chicago].

The development of therapeutic measures for the carotid artery occlusive syndrome makes the early diagnosis of this condition more important. The authors review observations on 57 patients with occlusive carotid disease. The records of 24 of them were obtained from the stroke study files of the Cornell medical and neurological services of Bellevue Hospital, and the records of the other 33 patients were obtained from the New York Hospital. In each of the 24 patients, the diagnosis was confirmed by carotid arteriography. The diagnosis in the 33 patients was established by carotid arteriography in 20 patients, by surgical exploration in 5, and by autopsy in 8. A history of a previous stroke was obtained in 15 patients. Transient ischemic attacks had occurred prior to demonstration of the occlusion in 22 patients. Episodic ipsilateral visual disturbance, alone or with associated contralateral hemiplegia, was described by 10 patients. Somnolence during the prodromal period occurred in 7 patients. The comparative measurements of retinal artery pressure and palpation of the carotid artery in the pharynx were the most reliable bedside diagnostic procedures. Diagnosis without arteriography is considered possible in a majority of instances.

Forty patients received no specific treatment. Eleven patients received anticoagulant drugs for longer than 4 months, and 6 patients had cervical ganglionectomy performed. No inferences can be drawn about the effect of anticoagulants and cervical ganglionectomy from so small a group of patients. The striking variability of the clinical picture and prognosis in individual patients with carotid artery occlusive disease is illustrated in 2 diagrams, one of which graphically records the natural history of patients not treated, and the other the history of patients who were treated.

It is in the stroke with acute catastrophic onset that a large percentage of the deaths or severe residual disabilities occur. In such instances the effects of anticoagulant therapy or surgery on the affected carotid artery are not at present encouraging. More emphasis should be placed on the preceding "minor" cerebral vascular episodes, which are, with the increasing enthusiasm for treatment, more likely to become the event leading to diagnosis. In 5 patients the transient ischemic attacks ceased spontaneously. The course of the disease can be deduced from 19 of the 57 patients, in whom more than 5 years have elapsed since the appearance of the first signs of cerebrovascular disease. Three died within a year; one died within 3 years, and three, 5 years after the first symptom. Three of these 7 deaths were not primarily due to carotid artery disease. The other 12 patients are alive from 5 to 18 years after their first symptoms. The majority of these patients had not received any specific treatment. The great variability of the symptoms of intermittent insufficiency and in the life span of these patients emphasizes the need for well-controlled studies of proposed therapeutic measures.

PEDIATRICS

Staphylococcal Infection in Infancy. C. Isbister. M. J. Australia 2:629-633 (Oct. 31) 1959 [Sydney].

In September, 1958, the New South Wales Department of Public Health, in Sydney, added staphylococcic infections to its list of notifiable infectious diseases. Included were staphylococcic mastitis, staphylococcic pneumonia, and staphylococcic infections occurring in infants under 4 weeks old. Notification of breast abscesses, staphylococcic pneumonia, and infant deaths from staphylococcic infections seemed a matter of urgency, since the main reservoirs of virulent epidemic strains of staphylococci in the community were the maternity hospitals. Owing to the baby's apparent inability to localize infection, quite trivial lesions must be treated with respect. The common infections of the first 2 weeks of life are conjunctivitis, pustular rashes, paronychia, nasopharyngitis with purulent discharge, redness of or discharge from the umbilicus, otitis media; infected skin abrasions, and indurated areas in skin. The more serious infections, tending to occur a little later, are abscesses, cellulitis, osteomyelitis; osteitis and septic arthritis, pneumonia, and pyelonephritis. The author feels that all clinical lesions from which coagulase-positive staphylococci can be cultured must be considered notifiable.

This paper is concerned chiefly with staphylococcic pneumonia in infants and children. Of 22 children with staphylococcic pneumonia whose records were analyzed, the histories of 5 are presented to illustrate the different clinical pictures. The first was an 8-month-old baby with acute fulminating staphylococcic pneumonia, possibly associated with influenza. The postmortem examination revealed extensive hemorrhagic consolidation of both lungs, and hemolytic Staphylococcus aureus, phage type 80, was grown from the lung in pure culture. The second patient was a 2-week-old baby, born in a maternity hospital in which several mothers with breast abscesses were treated at the time. This infant had multiple abscesses in both lungs.

Microscopic examination of sections revealed acute suppurative pneumonia with clumps of cocci in the lungs. Culture of lung tissue yielded a Staph. aureus, phage type 80. The third patient, a 5-week-old infant, had had abscesses since the age of 2 weeks. This infant recovered slowly, and roentgenologic examination revealed a localized pneumonic lesion in one lung. In the fourth baby localized lesions were followed by cyst formation. At the age of 5 months she suddenly became ill, with a very high temperature, grunting respiration, cough, and loose green stools. A roentgenologic examination of the chest revealed a large tension cyst or pneumothorax, and suggested the presence of some pneumonic process in the collapsed lung. The child steadily improved. Hemolytic Staph. aureus, phage type 80, was cultured from empyema fluid. The fifth case was one of pneumonia with empyema formation. A boy, 2½ years old, had a history of a cold with purulent nasal discharge for 2 weeks; this had commenced after his mother returned from the maternity hospital with a newborn baby with a pustular rash. The child's empyema was drained, and he slowly recovered. Hemolytic Staph. aureus was recovered from the empyema fluid and from the mother's breast abscess.

Nine of the 22 children were less than 2 months old, and of these 5 had been circumcised, either while clinical infection was present, or while they were still nasal and umbilical carriers. In all, 17 of the 22 cases could be traced to hospital infection. In 8 of the 9 patients aged under 2 months, local skin lesions or conjunctivitis had been present; the 9th had been circumcised when there were infections among the babies in that hospital. In order to throw further light on the reliability of diagnosis for notification of staphylococcic infections, the author reviewed the records of 69 children, less than 3 years old, admitted with pneumonia to a Sydney hospital in the course of the last 2 years. Among the 30 children who were less than one year old, the staphylococcic origin of the pneumonia was proved in 9; of 12 babies under 3 months, 3 were proved to have the staphylococcic form, and 9 probably had it.

Reduction of Staphylococcal Infection in the Newly Born. A. M. Hill, H. M. Butler and J. C. Laver. M. J. Australia 2:633-634 (Oct. 31) 1959 [Sydney].

In common with maternity hospitals elsewhere, the Royal Women's Hospital, Melbourne, has experienced the growing problem of staphylococcic infections in newborn infants. The following measures were taken to meet this problem: 1. A staphylococcic phage-typing laboratory was set up. 2. A survey of all sections of the hospital staff was made to ascertain the staphylococcic nasal carrier rate. 3. Recruits to the medical and nursing staffs were investigated before commencing duty in the hospital, and, if found to be nasal carriers, they were treated. 4. Nursing disciplines were tightened. Phage typing showed that there was no predominant epidemic strain among the staphylococci recovered from the infected babies or from the staff nasal carriers. But as there was some general correspondence among the various phage patterns of the staphylococci isolated from these 2 groups, nurses who were carriers of Staphylococcus pyogenes were treated by the local application of an antibiotic cream twice a day for one week.

When in spite of these measures the staphylococcic infection rate among babies continued to rise, the infection control committee started to investigate the use of hexachlorophene emulsion for the prevention of neonatal staphylococcic infection. Treatment was at first restricted to babies born in one of the hospital's 2 labor wards and was given only once, before transfer to the postnatal wards. This procedure reduced the number of infected babies in that unit by more than 25%. After this favorable response hexachlorophene emulsion was applied every 48 hours, but it was still given only to babies born in the one labor ward. During the next 4 weeks 230 of 249 babies in this ward were treated, and staphylococcic infection developed in only 4 (1.7%), whereas 5 of the 19 babies (26%) not treated became infected with staphylococci. Furthermore, in the second labor ward in which hexachlorophene emulsion was not used, 78 of 387 babies (20%) became infected with staphylococci. The use of hexachlorophene emulsion also reduced the number of babies who became nasal carriers of pathogenic staphylococci while in hospital.

In the labor ward the nurse swabs the entire surface of the baby with 2 ml. of hexachlorophene emulsion on a cotton swab, paying particular attention to the scalp, the skin creases of the neck, axillas, groins, and natal clefts. This swabbing is repeated with cotton wool moistened with warm tap-water. The lather obtained is wiped off with cotton wool, and the baby is dried. An additional 1 ml. of hexachlorophene emulsion is then wiped over the whole skin surface. In the ward for newborn babies this treatment is repeated at 2-day intervals. The stump of the cord should be covered with a sterile dressing at first. After this dressing is removed, the cord is painted daily with iodine. Apart from a demonstration bath immediately before discharge, no baby is bathed in the hospital. Cleansing, when required, is carried out by sponging with tap-water. Whereas in the 6 months before the use of the hexachlorophene emulsion the incidence of staphylococcic infections was 15%, in the first six months of its full employment it was only 1.3%.

Partial Thoracic Stomach in Childhood. J. B. Burke. Brit. M. J. 2:787-792 (Oct. 24) 1959 [London].

The author reports on 97 boys and 40 girls with partial thoracic stomach who attended the thoracic unit of the Hospital for Sick Children, London, between 1945 and 1955. One hundred thirty-two of the 137 children had a small intrathoracic loculus of stomach, and in the remaining 5 (all girls) the hernia comprised most of the stomach. The main symptoms in the 132 children were vomiting (dating from birth in 77%), hematemesis (in 89%), dysphagia (in 38%), and unsatisfactory gain in weight. Boys predominated in a ratio of 2.7 to 1 and were more severely affected than girls. The prognosis was very good in 74 (91%) of 81 children, aged less than one year. Dysphagia and narrowing of the esophagus were of serious prognostic significance. Of the 132 children with a small intrathoracic loculus, 33 had persistent organic fibrous contracture of the esophagus, 27 had variable narrowing of the esophagus probably due to spasm, and 27 did not have any esophageal narrowing (uncomplicated cases). Mental retardation was present in 10 children, 2 of whom had phenylketonuria and 4 had sucrosuria.

Sixty-eight children were treated medically, and 64 were treated surgically. At the time of follow-up, 9 months to 10 years after the institution of treatment, 41 (60%) of the 68 children treated medically were symptom-free (group 1), 21 (30%) had mild symptoms (group 2), 3 (5%) had fairly severe symptoms but a tendency to improvement (group 3), and only 3 (5%) had persistent severe symptoms (group 4). Thus, 90% were placed in groups 1 and 2 at the time of follow-up, which shows that medical treatment is satisfactory in most cases of partial thoracic stomach. Of the 64 children treated surgically, 24 (38%) were classified at the time of follow-up in group 1, 23 (35%) in group 2, 7 (11%) in group 3, and 10 (16%) in group 4. It is noteworthy that in only 12 of the 64 children treated surgically was there an immediate response to operation with cessation of symptoms. In the others, improvement had sometimes begun before surgical intervention was performed, but more often it was not evident until months or even years afterwards. This makes it difficult to assess the value of surgery. Persistent esophagitis, with or without stricture formation, is to be considered an indication for repair of the hernia. Children without esophageal narrowing and older children with strictures should be given a trial of medical management. The 5 children with a large right-sided intrathoracic loculus, in whom the cardia was found to be above the diaphragm and the hernia comprised most of the stomach, were operated on. Their response to surgical intervention was immediate, with complete relief of symptoms.

Clinical and Epidemiologic Considerations and Research in an Epidemic of Gastroenteritis with Staphylococcic Etiology Among Newborn Infants and Sucklings of a Maternity Ward. N. Nigro and U. Vignolo Lutati. Minerva pediat. 11:975-979 (Sept. 29) 1959 (In Italian) [Turin, Italy].

The authors report a clinical and epidemiologic study made among 35 newborn or suckling babies with hypertoxic gastroenteritis caused by staphylococcic infection, observed during a month in the maternity ward of a hospital in Turin, Italy. Twenty-seven babies who were treated in the hospital were transferred to the pediatric ward. The infection occurred in all instances between the 2nd and 6th days of life. Most of the babies were being breast-fed. All but 3 babies presented loss of body weight that ranged from 270 to 1,110 Gm. (about ½ to 2½ lb.) and was already manifest 2 to 6 days after the appearance of the clinical symptoms. Severe impairment of the general condition (pallor, facies hippocratica, nonelastic cutis with some edema, marked diminution of the panniculus adiposus, and depressed fontanel) and marked toxicity (with involvement of the central nervous system in some cases) were present in all the patients. The gastrointestinal symptoms followed the general symptoms within 2 or 3 days in most instances. Most of the babies presented diarrhea, 22 of the 35 were subject to vomiting, and more than half had fever. A relapse, with symptoms not as severe as in the first episode, was noted in 8 infants. Two infants, 7 and 10 days old, respectively, after clinical recovery from gastritis, suffered from obstructive jaundice. Ten of the 27 infants who were treated at the hospital died; nothing is known of the final outcome of the infection in 8 infants.

Bacteriological examination revealed the presence of a pure culture of massive, gram-positive cocci, which on agar formed round opaque colonies with smooth white margins, 2 to 3 mm. in diameter. The isolated germ grew well in broth at a temperature of 37 C, showing turbidity and sedimentation. On agar the germ developed on the surface, and in gelatin, with liquefaction of the medium at 20 C, it caused acidification and coagulation of milk. The germ likewise caused hemolysis in bacteriological mediums that contained blood (agar and broth); it caused coagulation of rabbit serum at 37 C and acidification (which produced no gas) of glucose, lactose, levulose, saccharose, maltose, mannitol, and glycerin.

The infants derived benefit from treatment with chloramphenicol and tetracycline; those that had relapses benefited from the administration of novobiocin and Signemycin. Total resistance of the cocci to Terramycin, Aureomycin, and the sulfonamides and partial resistance to penicillin and streptomycin were observed. The infection, which the authors believe may have been caused by germs carried into the maternity ward by healthy persons, was highly contagious. Prophylaxis with antibiotics of all those who come in contact with newborn babies who might be infected is advised. Breast feeding may be continued after disinfection of the mother with antibiotics.

High Frequency of Increased Blood Sugar Level in Children with Severe Toxic-Infectious Disease. R. Bulgarelli and R. Bruni. Minerva pediat. 11:895-904 (Sept. 15) 1959 (In Italian) [Turin, Italy].

Increased blood sugar level was observed in 9 of 26 children with a severe acute or subacute toxic-infectious disease. Six patients died of the disease. A meningo-encephalitic disease was present in 7 of the 9 patients with increased blood sugar level. Insulin was given to 3 patients, but without avail; an uncle of one patient and the grandmother of another had died of diabetes. The blood sugar was restored to normal level in the 3 surviving patients; there were no symptoms of diabetes on follow-up inspection after discharge. Correlation between the severity of the disease and the increased blood sugar level seems probable; thus, of 4 patients who had blood sugar levels higher than 200 mg. per 100 cc., only 1 survived. Increased blood sugar level was observed in patients in the final phase of tuberculous meningitis. Hypoglycemia was observed in only one infant, 6 months of age. The authors concluded that there are several factors which cause increased blood sugar level in patients with a severe and acute toxic-infectious disease, but the predominant factor seems to be neurogenic.

Report of a Rare Case of Whipple's Disease in Childhood. R. Bruni and L. Massimo. Minerva pediat. 11:935-943 (Sept. 22) 1959 (In Italian) [Turin, Italy].

A 10-year-old girl was hospitalized with a history of frequent vomiting and of loss of strength, appetite, and weight 2 months before admission. Subsequently her feces changed in consistency, color, and smell; vomiting became more frequent; and oliguria developed. The patient lost 6 kg. (13 lb.) in weight, and her condition remained unchanged during a 2-month hospital stay. Swollen lymph nodes at the root of the mesentery were the only pathological change observed at an exploratory laparotomy. These nodes were removed for microscopic examination. The postoperative course was normal. A combined treatment with pancreatic enzymes, vitamins, and cortisone had been instituted during hospitalization and was continued after discharge. Roentgenologic studies revealed slight dyskinesia of the small intestine, left kidney rotated on its axis with the pelvis in the anterior position, and presence of an ovoid mass between the spleen and the upper pole of the left kidney. Microscopic examination of resected lymph nodes revealed lymphatic and reticulohistiocytic hyperplasia and giant cells with a positive reaction on periodic acid staining. These findings suggested intestinal lipodystrophy (Whipple's disease) in the initial phase. The authors found in the literature only 2 such cases of Whipple's disease.

OPHTHALMOLOGY

Inheritance of Retinoblastoma in Ohio. M. T. Macklin. A. M. A. Arch. Ophth. 62:842-851 (Nov.) 1959 [Chicago].

This study on the family histories of all those children who had been born in Ohio between 1940 and 1956 and who had developed retinoblastoma by the end of 1958 revealed collateral lines affected in 10.5% of those whose cases have been regarded as sporadic. The mode of inheritance agrees with the interpretation that the gene is dominant, but in these families the average penetrance was much lower than that found by other workers. The mutation rate was 1.76×10^{-5} when all sporadic cases were included and 0.63×10^{-5} when only bilateral cases were included. The frequency of the disease, which is based on the ratio of affected persons (including the hereditary as well as the sporadic cases) born within a given time to the number of births occurring in that same period, was about 1 in 23,287 persons who survived to the age of one year.

The risk of producing offspring with retinoblastoma concerns 3 different groups. The first group includes those who know that others among their sibs or close relatives were affected. They should not have children, since their chance of passing on the gene is one-half, and the risk that any one of their offspring will be affected will be one-half times the degree of penetrance which the gene will show in the offspring. The second group includes those who have produced one child with the disease, although they themselves are normal, and there is no known case in the family apart from their affected child. This problem was faced by 145 sibships in this series. In 55 sibships no children were born after the first affected child. In the remaining 90 families in which subsequent pregnancies did occur, 6.67% had one or more affected children. The number of affected children born after the first affected child ranged from 1 to 5. The third group of persons are those who might inquire concerning their risk of bearing affected children, because they themselves represent isolated instances of the disease and have grown to maturity. It might be a phenocopy in them, in which case their children should be normal; it might be a somatic mutation, because most of those who survive have unilateral disease. Of

2 persons representing the third group in this series, each has had one child, and neither child has been affected although still under 3 years of age.

Diabetic Retinopathy and the Pituitary. E. J. Ranke. A. M. A. Arch. Ophth. 62:859-863 (Nov.) 1959 [Chicago].

The author studied the occurrence of diabetic retinopathy in 66 patients (38 women and 28 men) with pituitary tumor. The majority of the patients were between 21 and 40 years of age at the time of recognition of symptoms establishing the clinical onset of the tumor. Thirty of the 66 patients had coexisting diabetes. In 27 of the 30 patients the diabetes was associated with eosinophil tumor, in 2 with basophil tumor, and in 1 with chromophobe tumor. Twenty-one of the 30 diabetics required treatment with insulin; the remaining 9 patients were newly discovered diabetics, as determined by abnormal glucose tolerance tests, and had not required insulin at that time. The time of appearance of diabetes during the course of pituitary tumor proved to be variable. The majority of the patients developed diabetes within the first 6 years after onset of the pituitary tumor. The longer the duration of the pituitary tumor, the greater was the percentage of patients developing diabetes.

Two patients of the entire group of 66 patients had diabetic retinopathy. The 30 patients with pituitary tumor and diabetes were compared with a similar group of 30 diabetic patients without pituitary tumor, but matched identically for age, sex, and duration of diabetes. Results showed that 8 of those patients who had diabetes but no pituitary tumor developed diabetic retinopathy, whereas only 2 of those patients with diabetes and pituitary tumor developed diabetic retinopathy. Pituitary tumors do not seem to contribute to the development of diabetic retinopathy. Whatever the pituitary hormonal influence might be in promoting the development of diabetes, these same diabetogenic factors do not seemingly contribute to the production of diabetic retinopathy. This rarity of diabetic retinopathy in patients with pituitary tumor who develop diabetes mellitus should be considered before pituitary ablation is considered for the removal of diabetogenic factors in a patient with diabetic retinopathy.

Elementary-Body Virus Isolated from Clinical Trachoma in California. L. Hanna, P. Thygeson and E. Jawetz. Science 130:1339-1340 (Nov. 13) 1959 [Washington, D. C.].

The authors present observations on a 36-year-old man, a long-time resident of California, who in January, 1959, complained that his left eye was red, and who had a moderate yellow discharge and a nontender left preauricular lymph node. His physician prescribed 1% chloramphenicol eyedrops, which he instilled for the next 26 days, with some symptomatic improvement. On Feb. 12, a similar conjunctivitis developed in the right eye, with marked photophobia. Neomycin-polymyxin eyedrops were administered for 4 days. On Feb. 16 the inflammation in the left eye suddenly increased markedly, and gross keratitis appeared. Clinical examination on Feb. 17 revealed bilateral papillary hypertrophy, with buried follicles of the upper tarsi, microscopic pannus, corneal infiltrates, and palpable preauricular lymph nodes. Scrapings from the upper tarsal conjunctivas showed many inclusions typical of trachoma. Bacterial cultures were negative, but a virus was isolated from conjunctival scrapings by injection of the material into the yolk sac of embryonated eggs. Morphologic and serologic studies identified the virus as belonging to the psittacosis-lymphogranuloma group. The elementary bodies conformed in size and staining properties with those grown by others from trachoma patients. Four monkeys (Macaca cynomolgus) were inoculated in one eye with a 20% yolk-sac suspension of 6th-passage virus. Follicular conjunctivitis developed in all monkeys 2 to 6 days later, and the conjunctival scrapings contained many typical inclusion bodies. The patient was treated with topical application of tetracycline and oral administration of methylsulfapyridazine (500 mg. daily) for the next 8 weeks, with gradual disappearance of all clinical and microscopic signs of trachoma. This appears to be the first isolation of an elementary-body virus of the psittacosis-lymphogranuloma group ("trachoma virus") from a typical case of trachoma arising in the United States.

THERAPEUTICS

A Comparison of the Diuretic Action of the Chlorothiazide Analogues. D. S. Young, T. M. Forrester and T. N. Morgan. Lancet 2:765-768 (Nov. 7) 1959 [London].

The authors compared the diuretic action of chlorothiazide, hydrochlorothiazide, and hydroflumethiazide in 10 healthy male medical students without evidence of renal disease. These men were allowed a fixed and known fluid intake. The urine of each man was collected over a period of 24 hours on 4 separate occasions. In the first control period no drug was given, and in the subsequent 3 periods the effects of 2,000 mg. of chlorothiazide, 150 mg. of hydrochlorothiazide, and 150 mg. of hydroflumethiazide were compared. At least 7 days elapsed for each man between successive experiments to allow the restoration of normal body-fluid composition. The results showed that all 3 drugs caused diuresis with similar changes in the composition of the urine, except that hydrochlorothiazide and hydroflumethiazide were effective in smaller dose and caused less potassium and bicarbonate loss than chlorothiazide. The actions of hydrochlorothiazide and hydroflumethiazide were more prolonged than that of chlorothiazide, particularly concerning the excretion of sodium and chloride. The prolonged action and the smaller effective dose of hydrochlorothiazide and hydroflumethiazide can be explained by the finding that chlorothiazide is less completely absorbed by the intestine and more rapidly eliminated in the urine than are hydrochlorothiazide and hydroflumethiazide.

Antimicrobial Therapy of Non-Tuberculous Pulmonary Infection. C. E. van Rooyen and R. C. Dickson. Canad. M. A. J. 81:706-710 (Nov. 1) 1959 [Toronto].

The authors state the guiding principles of antibiotic therapy in nontuberculous pulmonary infections: (1) to know the natural history of the disease under treatment; (2) to know how this is modified by antibiotics or chemotherapy; and (3) to take the necessary steps to find out why, in certain cases, the probable course of the disease cannot be arrested. A careful watch should be maintained on pulmonary changes, since no antibiotic administered by any route can penetrate a thickened pleura or a lung abscess.

The merits of antibiotics currently used to treat infections due to penicillin-resistant organisms are listed, as established at the Sixth Symposium on Antibiotics held in Washington, D. C. Kanamycin is active against staphylococci, Escherichia coli, and other organisms, but not against streptococci, pneumococci, and Pseudomonas organisms; its toxicity is manifest on the 8th nerve and on the kidneys. Erythromycin propionate acts best against rapidly multiplying organisms, although resistance can develop in vitro during the treatment. Vancomycin is the most potent antibiotic against resistant staphylococci; its intravenous administration to children is sometimes accompanied by painful phlebitis. Ristocetin has a much more powerful effect than erythromycin and penicillin. Novobiocin has a great value in severe staphylococcic infection.

The authors call attention to the problems resulting from antibiotic therapy. They report the successful treatment of 70 patients with bronchitis to whom tetracycline was administered in the dose of 250 mg. every 6 hours during 5 days, in a total dose of 5 Gm. Examination of the stools during the treatment showed temporary suppression of normal intestinal flora and slight increase in Candida albicans without evidence of moniliasis; staphylococci appeared in the stools without the onset of diarrhea. The sulfonamides, relegated to a second plane by the new antibiotics, represent a useful second line of defense against infections. The use of antibiotics as a preventive therapy is not recommended. So far as lung infections are concerned, prophylactic antibiotics may do more harm than good in 3 situations: (1) certain postoperative states; (2) bulbospinal poliomyelitis with respiratory complications; and (3) cerebrovascular accidents. The association of cortisone with antibiotics may suppress the inflammatory defense mechanism and so aggravate the severity of pulmonary infection. In pneumonia this association is beneficial, provided that an effective antibiotic is administered.

A Comparison of Prednisolone with Aspirin or Other Analygesics in the Treatment of Rheumatoid Arthritis: Report by the Joint Committee of the Medical Research Council and Nuffield Foundation on Clinical Trials of Cortisone, ACTH, and Other Therapeutic Measures in Chronic Rheumatic Diseases. Ann. Rheumat. Dis. 18:173-188 (Sept.) 1959 [London].

A study is reported on the effect of prednisolone, compared with the effect of aspirin or other analgesics, in the treatment of 84 patients with rheumatoid arthritis. A few patients defaulted, died, or were withdrawn from the trial, and the results of 2 years of treatment are based on the analysis of 77 patients, 41 of whom were originally allocated to prednisolone therapy and 36 to analgesics. The patients treated with prednisolone showed an early significant improvement in both clinical and laboratory indexes of inflammatory polyarthritis, and this improvement, though less, was still present to a significant extent at the end of 2 years. In the patients treated with analgesics, the frequency of radiologic signs of erosive joint disease in the hands and feet increased significantly over the 2 years, whereas there was no significant change in the group treated with prednisolone. In many patients treated with prednisolone, the agglutinating titer in the sheep-cell test rose during the 2 years of treatment, whereas such a rise occurred in only a few patients treated with analgesics. Two patients treated with analgesics died of heart failure. Five patients treated with prednisolone developed major complications—2 developed psychosis and 3, peptic ulceration. These major complications occurred in patients receiving a daily dose of 20 mg. (or more) of prednisolone. Patients receiving prednisolone also gained weight, and showed some rise in blood pressure and a tendency to mooning of the face. During the trial the mean daily dose of prednisolone was gradually reduced from 17.4 to 10 mg., and more than half of the patients on prednisolone therapy were also receiving aspirin or other analgesics.

The joint committee believes that the administration of prednisolone, instead of, or in addition to, analgesics, to certain patients with rheumatoid arthritis for a period of 2 years will, on an average, improve their functional capacity and general well-being and reduce the incidence of erosive joint damage. More patients, however, are likely to show a rise in sheep-cell agglutination titer, and the significance of this therapy for the future of the patients is not yet known. Undesirable side-effects are likely to occur if the daily dose of prednisolone approaches 20 mg. per day. For the committee, the highest acceptable dose for long-term therapy is 10 mg. of prednisolone per day.

Further Experience with Oral Therapy in Diabetes. K. L. Granville-Grossman, S. Crawfurd, M. F. Crowley and A. Bloom. Brit. M. J. 2:841-847 (Oct. 31) 1959 [London].

The authors report on 113 patients with diabetes mellitus, 30 of whom, between the ages of 34 and 89 years, were treated with metahexamide, a sulfonylurea compound; 75, between the ages of 38 and 86 years, were treated with chlorpropamide; and 8, between the ages of 47 and 75 years, were treated with dimethylbiguanide. In 20 of the 30 patients, the diabetes was well controlled by an initial dose of 300 mg. of metahexamide daily, later reduced to 50 to 200 mg. of the drug daily. On this dose the blood sugar levels remained within the normal range, and the urine became virtually free of sugar. The remaining 10 patients were therapeutic failures. No rash, gastrointestinal upset, or evidence of blood dyscrasia was observed after treatment with metahexamide, and no patient complained of symptoms referable to hypoglycemia. Jaundice, however, was observed in one patient after treatment with this drug. Chlorpropamide was successful in controlling the diabetes in 50 of the 75 patients treated with this drug. The blood sugar level remained within normal limits, and the urine became free from sugar for most of the day while these patients were receiving the drug, which was given in one dose of 500 mg. in the morning daily; the dose was reduced to 200 mg. daily if a satisfactory hypoglycemic response was obtained. Twenty patients were therapeutic failures, and in 5 patients administration of chlorpropamide was discontinued because of intercurrent illness or side-effects consisting of a generalized rash suggestive of sensitivity dermatitis. Seven of the 8 patients treated with dimethylbiguanide had a satisfactory hypoglycemic response to a daily dose of 1 to 3 Gm. of the drug. Five of the 8 patients complained of nausea, vomiting, or diarrhea, necessitating withdrawal of the drug in 3.

These findings suggest that metahexamide is a well-tolerated hypoglycemic agent, effective in patients with mild diabetes mellitus with onset at maturity. Its action is more sustained than that of tolbutamide, so it can be administered once daily. Chlorpropamide is a more effective oral hypoglycemic agent than tolbutamide, and needs be given only once a day. It is well tolerated, but occasionally gives rise to sensitivity reactions. Dimethylbiguanide is an effective hypoglycemic agent but is not well tolerated by mouth. Half-life studies on metahexamide showed that the drug disappeared from the plasma more rapidly in normal persons than in patients with diabetes mellitus. Many patients with diabetes mellitus, particularly those with a recent onset of the disease, remained controlled by simple dietary restriction alone after a 6-week course of oral therapy, though the length of remission varied. Three patients with diabetes mellitus, who failed to respond to either metahexamide or chlorpropamide or phenethylbiguamide (Phenformin) when given separately, were stabilized on a combination of chlorpropamide or metahexamide with Phenformin.

Chlorpropamide in the Treatment of Diabetes Mellitus. D. Jackson and W. Oakley. Lancet 2:752-754 (Nov. 7) 1959 [London].

The authors report on 126 patients with diabetes mellitus, who were treated with chlorpropamide (Diabinese) at the diabetic clinic of the King's College Hospital in London. Of the 126 patients, 54 had mild diabetes not requiring insulin therapy, 48 had been controlled with less than 40 units of insulin per day, 13 had required more than 40 units of insulin per day, and 11 had acute ketotic onset. Forty-two of the 54 patients, 35 of the 48 patients, 6 of the 13 patients, and 6 of the 11 patients, i. e., a total of 89 patients, obtained satisfactory control of their diabetes on chlorpropamide therapy. The initial dose of chlorpropamide given to these patients varied from 250 to 375 mg. The change from insulin to chlorpropamide was effected in 2 different ways. In 33% of the patients the dose of insulin was reduced by 50%, and 100 to 250 mg. of chlorpropamide was administered together with the reduced dose of insulin, which was further reduced over a period of 7 to 14 days if good results were obtained. In the remaining patients, the insulin administration was stopped completely, and the first dose of chlorpropamide administered on the following day. The carbohydrate allowance in the patients' diet varied from 90 to 200 Gm. per day.

The maximum period of treatment with chlorpropamide in these patients was 7 months, and so far only 5 have had a relapse after a period of good control on chlorpropamide therapy. Two of these 5 patients were young ketotic diabetics who were started on chlorpropamide therapy during the period of increased carbohydrate tolerance which often follows the institution of insulin therapy, and in the other 3 patients there were complications caused by some unrelated medical condition. Of 17 patients who had relapses on tolbutamide treatment, 15 responded well to chlorpropamide. These data show that chlorpropamide has a greater range of activity than tolbutamide and is effective in patients in whom relapses occur on tolbutamide therapy. The incidence of toxic effects of chlorpropamide is low when the maximum dose does not exceed 375 mg. per day. The patient's age and the duration of diabetes mellitus had no bearing on the response to chlorpropamide in these patients.

Both tolbutamide and chlorpropamide were used in the treatment and suppression of steroid-induced diabetes in 5 patients. It is too soon to analyze completely the results obtained in these patients, but preliminary results suggest that steroid-induced diabetes can be suppressed by the administration of either tolbutamide or chlorpropamide in the early stages of the disease.

Nitrogen Mustard and Adrenocorticotropic Hormone in the Management of Patients with Incurable Carcinoma. M. W. Wolcott and W. A. Shaver. South. M. J. 52:1375-1379 (Nov.) 1959 [Birmingham, Ala.].

Eighty patients with far-advanced cancer, with either focal or distant metastases, were given a combined corticotropin (ACTH) and nitrogen mustard therapy. Nitrogen mustard was administered in daily doses of 0.1 mg. per kilogram of body weight for 5 days; corticotropin was given intramuscularly in doses of 60 mg. every 6 hours, beginning 18 hours prior to the first dose of nitrogen mustard and continued for 5 days, and then in decreasing doses over the next 2 days. Supportive treatment with antibiotics, blood transfusions, and intravenously administered fluids was given as indicated. Usually, the combined treatment was resumed after an interval of 4 to 6 weeks, but this interval was increased to 2, 3, and 4 months in some patients who showed a good response to treatment. In this series of 80 patients other treatments were also applied, such as palliative surgery in 31 and roentgenotherapy in 50. Excellent results were obtained in 10% of the patients. One patient with carcinomatosis of the peritoneal cavity and another with lymphosarcoma are both living and well after 3 years. Three patients with carcinoma of the lung are living, 2 of these after a year and a half and 1 after 6 months, without evidence of recurrence at this date. Fifteen patients (18.7%) had good palliation; all have died. Nineteen patients (23.8%) had fair palliation; all have died. Thirty-eight patients (47.5%) had poor palliation; all have died.

The authors believe that the combined treatment with corticotropin and nitrogen mustard has a limited, but definite, place in the palliation of advanced cancer. Its value was more apparent in patients with bronchogenic carcinoma. The best results were obtained in patients in whom nitrogen mustard therapy was immediately given after surgical treatment. A failure to obtain some relief with the first course of treatment with nitrogen mustard and corticotropin contraindicates subsequent courses. The toxicity of nitrogen mustard was reduced by the concomitant use of corticotropin.

PATHOLOGY

Post Mortem Studies on Coronary Atherosclerosis in One Population Group. D. M. Spain and V. A. Bradess. Dis. Chest 36:397-406 (Oct.) 1959 [Chicago].

Postmortem studies were made on the hearts from consecutive Medical Examiner's autopsies in Westchester County, New York. The coronary arteries were sectioned at 2-mm. intervals, examined, and graded by an observer who had no knowledge of the sex, age, race, occupation, and mode of death of the persons in question. After this examination the findings were related to the respective categories of data. The incidence of coronary atherosclerosis in sedentary and physically active "normal" persons was studied in men, between the ages of 30 and 60 years, who had died suddenly in traffic or industrial accidents. The sedentary group was represented by 82 specimens, and the active life group by 84. Three degrees of atherosclerosis were established, and their distribution studied in relation to six 5-year age groups. The incidence of the different degrees of atherosclerosis was similar in both the sedentary and the active life samples of each age group. The distribution of the average grading of coronary atherosclerosis was not significantly different in relation to the 2 variables.

The relative incidence of atherosclerotic and thrombotic coronary occlusion in sudden death was studied in the entire series of autopsies. There were 367 men and 43 women, with the great majority in the 39-to-69-year age bracket. In 50 of the 310 cases of atherosclerotic occlusion and in 17 of the 100 cases of thrombotic occlusion, there had been physical activity prior to the attack, which means an over-all percentage of 30%. Among the 43 women, atherosclerotic occlusion had occurred in 7 under 50 years of age and in 24 over 50 years, whereas the number of thrombotic occlusions was, respectively, 3 and 9. Among the 277 men who had died of atherosclerotic occlusion, 68 had had infarction; 41 had performed some strenuous activity prior to death; 11 had both had infarction and had exerted strenuous activity. Of the 90 men who had died of thrombotic occlusion, 31 had had infarction and 15 had had strenuous activity; in 8 of these 15 the exertion was associated with infarction. Six of those with atherosclerosis and 2 of those with thrombotic occlusion had performed some unusual strenuous activity. The authors conclude that strenuous physical activity prior to sudden death from either atherosclerotic or thrombotic occlusion is less frequent than is generally believed, and does not appear to be an important factor, except in occasional instances. Acute coronary thrombosis is primarily a complication of, and intimately related to, the atherosclerotic process.

Three groups of autopsied persons were studied in relation to the comparative degree of aortic and thrombotic atherosclerosis. In the first group there was a lower grading of aortic than of coronary atherosclerosis; in the second there was an equivalent grading of both types; and in the third there was a higher grading of aortic than of coronary atherosclerosis. The incidence of these gradings was analyzed with reference to 2 age groups—those from 30 to 50 years and those from 50 to 70. Of the 46 women in the 30-to-50-year age group, 21 had a higher degree of aortic than of coronary atherosclerosis, 19 had approximately the same degree of both, and 5 had a higher degree of coronary than of aortic atherosclerosis. Among the 77 men in the same group, these proportions were reversed. In the over-50 age group the relative gradings of coronary atherosclerosis in the women tended to approach those in the men, and the relative relationship of coronary to aortic atherosclerosis was almost equally divided in the 2 groups. The general and the specific differences indicate that estrogens are a factor in the atherogenic process and may be more specifically related to coronary than to aortic atherosclerosis. They may also indicate that a certain local vascular factor is important in determining the differential rate of atherogenesis.

Autopsy data on 50 suicides were compared with the data on 50 accidental deaths. The absolute and relative incidences of coronary atherosclerosis were very similar in both groups. Since suicide is supposedly an indicator of emotional disturbance, these results do not support the belief that emotional stress had an important role in the pathogenesis of atherosclerosis, although there are other aspects, such as the effect of stressful situations on persons with underlying advanced coronary atherosclerosis, which were not included in this study.

Primary Heart Tumors: Two Cases. K. Maurseth. Nord. med. 62:1452-1455 (Oct. 1) 1959 (In Norwegian) [Stockholm].

Primary heart tumors are rare and are seldom diagnosed before death. Primary benign heart tumors are 3 to 4 times as frequent as the malignant. The primary malignant tumors of the heart described have been sarcomas of various types, equally apportioned between ventricle and atrium. About half of the primary benign heart tumors are myxomas, which occur almost exclusively in the atrium and are mostly polypoid. Rhabdomyomas, fibromas, lipomas, and angiomas have also been reported. Most heart tumors are accidental findings. Often even large tumors give few symptoms. The first of the 2 cases of primary heart tumor seen in the Rikshospital in Oslo in 1958 was that of a woman, aged 32 years. Cerebral symptoms dominated the picture. Angiography of the carotid showed an expansive process of walnut size in the right parietal-occipital region, with presumably several smaller similar processes. The excised plum-sized tumor was histologically diagnosed as metastasis from a slightly differentiated malignant tumor. Death soon ensued. The polypoid heart tumor found at autopsy almost filled the left atrium and extended through the mitral ostium into the ventricle. The histological diagnosis was fibrochondroangioma. In the second instance, in a man, aged 50 years, who died of a reticulosarcoma, autopsy disclosed a tumor on the anterior surface of the right ventricle. The diagnosis was cavernous hemangioma. Angiography is the best aid in the diagnosis of polypoid intracardial tumors.

Observations on Thrombosis and Endothelial Repair Following Application of External Pressure to a Vein. H. R. Robertson, J. R. Moore and W. A. Mersereau. Canad. J. Surg. 3:5-16 (Oct.) 1959 [Toronto].

The effects of pressure applied to the external surface of the inferior vena cava were observed in an experimental study on 450 rats. By varying the amount and duration of pressure, it was possible to estimate the fragility and the recuperative power of the endothelium as well as the degree of injury necessary to produce thrombosis. The animals were anesthetized with pentobarbital (intraperitoneally), and the vena cava was exposed by gently displacing the intestine. A sterilized pressure foot, approximately 4 mm. in diameter, was applied to the surface of the vein. If the pressure was to be maintained for more than a few minutes, the abdomen was closed about the pressure foot in order to prevent dehydration. For observation of the immediate effects, the vein was stained and fixed as soon as the pressure foot was removed. For observation of progressive changes, groups of animals were anesthetized and their veins prepared at different intervals after removing the pressure and closing the abdomen. Eighty-six specimens, prepared and examined in groups at different intervals, served as controls.

No change was noted in the venous endothelium under a 10-second-long pressure of a 5-Gm. weight. A weight of 10 Gm. applied for 30 seconds, or 50 Gm. applied for 10 seconds, regularly produced localized lesions. In 11 rats examined 5 or more hours after removal of the weight, the endothelium appeared normal, which suggests that the changes are reversible. Weights of 100 and 200 Gm., applied to the vena cava during 1 hour and 3 hours, respectively, had fundamentally the same effects, namely, destruction of the endothelial layer with frequent formation of platelets and white blood cell thrombi. Repair by means of endothelial cellular ingrowth was observed in 54 rats to whose venae cavae a 100-Gm. pressure was applied for one hour. At 24 hours the first signs of repair were seen in the development of nucleoli in the endothelial cells surrounding the injured zone. By 48 hours mitotic figures had appeared in the surrounding cells, and actual division could be seen. By 144 hours mitosis had ceased, a few nucleoli and endothelized thrombi remained, and the cells were still closely packed and jumbled.

The authors suggest that the cause of thrombosis in humans may in certain cases be traced to the effects of direct pressure upon the vein. This may be the mechanism of thrombophlebitis occurring in persons who sit in a cramped position for a long time, or in those whose calves are compressed, as when they lie on an operating table. It is probable that as a result of unnoticed injuries the process of endothelial damage, thrombosis, and repair is constantly taking place in various parts of the body. The fact that thrombophlebitis is not an extremely common condition strongly suggests that trauma alone is seldom sufficient for propagation of the thrombus, which is the essential feature of thrombophlebitis. Some other factors, still unidentified, must be present in order to permit or to stimulate progression of the thrombus that may have been initiated by trauma.

RADIOLOGY

Roentgenologically Controlled Placement of the Needle in the Trigeminal Root for the Treatment of Tic Douloureux. T. Perl and A. Ecker. Am. J. Roentgenol. 82:830-839 (Nov.) 1959 [Springfield, Ill.].

Tic douloureux is a type of paroxysmal facial pain, and it occurs usually in patients over 40 years of age. There is a trigger zone, usually in the skin or mucous membrane served by the second and third divisions of the trigeminal nerve, the lightest touch of which precipitates the pain. The production of analgesia of the trigger area usually prevents further attacks. The authors describe a method of inserting a needle into the posterior root of the gasserian ganglion in order to inject the area with alcohol and produce numbness. A preliminary roentgenographic study is first made to determine the exact position of the head and the entry point of the needle. After the needle is inserted, further roentgenographic study indicates the relationship of the needle tip to the base of the skull and permits accurate adjustment of its depth. Procaine (2%, 0.03 cc.) is then injected to determine the position of the needle within the posterior root. Therapeutic injections of 0.05 cc. of absolute alcohol are finally made as indicated by careful sensory and motor testing.

The authors have used this method in 61 patients with trigeminal neuralgia, one of them with bilateral trigeminal neuralgia, during the period from October, 1954, through October, 1958. Numbness was produced in all patients, and pain was completely relieved initially. Pain recurred in 10 patients, and another injection was necessary. One of the patients underwent surgical rhizotomy later. Eight patients presented total corneal anesthesia, 2 presented brief periods of superficial corneal abrasion, but in no case was there keratitis or the need for tarsorrhaphy. Corneal sensation returned after one year in one patient. About half of the patients have had postinjection paresthesias; of these, only 3 were severe.

A Safe and Practical Intravenous Method for Abdominal Aortography, Peripheral Arteriography and Cerebral Angiography. I. Steinberg, N. Finby and J. A. Evans. Am. J. Roentgenol. 82:758-772 (Nov.) 1959 [Springfield, Ill.].

A safe and practical intravenous method of abdominal aortography, peripheral arteriography, and cerebral angiography, based on physiological principles learned during angiocardiography, is described. By this method organic iodides are injected rapidly and simultaneously in both arms with special syringes attached to Robb-Steinberg cannulas; the patient is ordered to "stop breathing," and a 2-second exposure for abdominal aortography is made. If peripheral arteriography is desired, another exposure may be made, either with a portable roentgenographic apparatus or with another tube. Standard grid cassette technique for lower extremity roentgenography suffices. The procedure may be repeated after a short interval if the patient has tolerated well the first procedure. If the peripheral circulation at the bifurcation of the iliac arteries is desired, the Bucky grid carriage may be shifted to include the extremities, and another injection made.

The first successful abdominal aortogram, with rapid, bilateral, simultaneous intravenous injection of concentrated contrast material, was made in March, 1959. Twelve additional patients, reported on in this study, have been seen since then, and in each instance the abdominal aorta and its branches were visualized. Since the submission of this study for publication in May, 1959, the method has been successfully employed in additional cases, raising the total number to 52. The abdominal aorta and peripheral arterial circulation were visualized in every case.

The optimal dose of concentrated contrast material has been established by the authors at 1 cc. per kilogram of body weight. Eleven of the 13 patients reported on suffered a mild and transient reaction to the injection. Reactions can be diminished markedly if a calm, reassured, nonapprehensive attitude is used. Aneurysmal and occlusive disease of the abdominal aorta and branches can be readily diagnosed by this method, facilitating the appropriate treatment for each patient. Cerebral angiography via the intravenous route, especially when biplane studies are made, will open a new field of diagnosis, and vascular malformations and displacement of cerebral structures may furnish clues to hitherto unrecognized syndromes of brain disease. Angiographic studies to locate subdural and cerebral hematomas after cerebrovascular accidents may become routine. The method described has distinct advantages over the translumbar, carotid, and vertebral arterial injection routes, which have sometimes been associated with serious complications and occasionally with death. The intravenous method of abdominal aortography and peripheral arteriography may be employed in almost every radiologic department, since conventional roentgenographic equipment is all that is required.

Hyperostosis of the Basilar Part of the Cranium in the Clinical and Roentgenologic Picture of Thalassemia. E. Durando and E. Grassi. Minerva pediat. 11:905-909 (Sept. 15) 1959 (In Italian) [Turin, Italy].

The authors report on 5 patients, aged between 1 and 3 years, with thalassemia or familial erythroblastic anemia (Cooley's anemia). Pallor appeared from the first days of life in 3 patients, from the third month in 1, and from the fourth month in 1. Retarded body growth was noted in 2 children. Roentgenologic examination of the cranium revealed thickening of the frontal bone in one patient, of the frontal and occipital bones in one, and of the vault of the cranium in one. It also showed marked hyperostosis of the vault of the cranium and, in particular, of the frontal and parietal bones in one. The main roentgenologic feature common to all 5 patients was the hyperostosis of the basilar part of the cranium. This lesion is often more pronounced than any other skeletal change. The authors believe that hyperostosis of the basilar part of the cranium is an essential, and not a secondary (as hitherto considered), diagnostic feature of Cooley's anemia.

The Clinical Significance of Arthrography of the Humeroscapular Joint. M. J. Kingma. Arch. chir. neerl. 11:261-265 (no. 3) 1959 (In English) [Arnhem, Netherlands].

The author, in collaboration with the radiologic department of the Wilhelmina Hospital in Amsterdam, investigated the problem of whether arthrography of the humeroscapular joint would improve the diagnosis of lesions of this joint, particularly the rupture of the rotator cuff. He shows that the radiologist can estimate the size and localization of the rupture. In addition, the radiologist will attempt to obtain by planigraphy or stereography exact information on the localization and extent of the defect. Thus, arthrography is capable of demonstrating or excluding complete cuff rupture. The author had occasion to compare arthrographic findings with surgical findings in 17 instances; the arthrographic indications were always confirmed. The objection might be raised that complete cuff rupture can well be diagnosed without an arthrogram. This is true only in cases that show the classical picture with all its symptoms. In other cases a diagnosis based exclusively on clinical findings is unreliable. Arthrography is indicated in cases in which abduction of the arm is still difficult 2 or 3 weeks after a trauma of the shoulder. Arthrography is also indicated in long-standing shoulder complaints.

Calcified Adrenal Cysts. A. J. Palubinskas, W. R. Christensen, J. H. Harrison and M. C. Sosman. Am. J. Roentgenol. 82:853-861 (Nov.) 1959 [Springfield, Ill.].

The cases of 4 patients (2 men and 2 women), 46 to 55 years of age, with benign adrenal cysts are reported. Approximately 80 cases of this disease have been published in the literature, and in only 3 instances was a correct preoperative diagnosis made on the basis of roentgenologic findings; in 2 of them, the most important feature was a thin laminar calcification of the cyst wall. The 4 cases reported by the authors showed this characteristic calcification. Symptoms or the past history of the patients are seldom revealing as far as the diagnosis is concerned. The diagnosis in all 4 cases reported here, and in some of the cases reported in the literature, was made on the basis of a mass, observed on roentgenologic examination, localized in the adrenal region, the periphery of which was outlined by curvilinear calcification. The incidence of calcified adrenal cysts seems to be 50% higher in women than in men; they occur in about equal numbers on the right and left sides. The majority of the cases concern patients in the 30-to-60-year age group, but the finding has been reported in all age groups from 2 months to 70 years. Reported size has varied from that "of a boy's marble" up to 30 cm. in diameter. The cysts may be unilocular or multilocular, and the contents vary from translucent fluid to dark gelatinous material mixed with tissue debris. The wall components are generally dense fibrous connective tissue, which may be hyalinized or may rarely show amyloid degeneration. The thickness of the wall is generally 1 to 5 mm., though some walls measuring 1 and 3 cm. have been reported. A variety of other cellular elements have been reported as components of the wall.

One-third of the cases of calcified adrenal cysts noted in the English literature show calcification microscopically, and in one-sixth this calcification is visible [illegible]. The paucity of reports in [illegible] manifestation of the clinical silence characteristic of these cysts rather than of their true rarity. The authors believe that, if a thin laminar calcification at the periphery of a soft tissue mass in the suprarenal gland is observed on roentgenologic examination, the demonstrated tumor is cystic and benign, and arises in or from the adrenal gland.

BOOK REVIEWS

Pediatric Pathology. By Daniel Stowens, M.D., Pathologist, Children's Hospital Society of Los Angeles. Cloth. $20. Pp. 676, with 374 illustrations. Williams & Wilkins Company, 428 E. Preston St., Baltimore 2, 1959.

As stated in the preface, there is a need for a book devoted to the anatomy of diseased children. Only occasionally are pathologists given the opportunity of spending most of their time studying diseases of children. Much of the information and photographic material presented here was collected during the years the author spent as registrar of the American Registry of Pediatric Pathology at the Armed Forces Institute of Pathology, Washington, D. C. A certain amount of clinical material is included with most subjects discussed to help correlate the morbid anatomy with the clinicians' experience. The book is predominantly concerned with processes about which there has been recent rapid development of knowledge and other processes that are still in the research-hypothesis stage. The author avoids discussing many subjects with the statement that these problems are already amply covered in existing texts. This leaves most of the work for the more important description of pathology of diseases that have recently become more completely understood. Where older hypotheses and clinical experience are unable to explain known anatomic distortion, the author presents hypotheses that do not conflict seriously with known clinical, laboratory, and research findings. This should be of great help to those who must sometimes explain seemingly unrelated phenomena in the course of children's diseases. Some of the author's hypotheses and descriptions may arouse howls of disagreement, but he is refreshingly aggressive in suggesting that they serve the purpose of calling attention to problems that previously did not seem to exist. The discussion of sudden death associated with respiratory inadequacy in infants is particularly striking.

Some of the rare diseases are discussed in glossary form, but the bibliography for such processes is usually sufficient to indicate sources of further reference. The diseases considered occur all over the world. The text is abundantly illustrated with the usual excellent detailed photographs from the Armed Forces Institute of Pathology. The pictures are mostly photomicrographs and will be of greatest value to the pathologist, although they should be of help to the clinician who conscientiously tries to understand the anatomy associated with abnormal clinical and laboratory findings. This book should help pediatricians and general practitioners to realize that the pathologist can be helpful in the study of some diagnostic problems. The appendix consists of a classification of the diseases of the first 10,000 patients about whom information is entered in the files of the American Registry of Pediatric Pathology. Most of this information was collected from 1954 to 1956.

The style is pleasant. The detailed analyses of particular problems are still found principally in medical journals, but this book should fill a serious need for a general textbook on the extent and character of pediatric pathology and should be in the library of all pediatricians, pathologists, county medical societies, and hospitals.

Jewish Medical Ethics: A Comparative and Historical Study of Jewish Religious Attitude to Medicine and Its Practice. By Rabbi Dr. Immanuel Jakobovits. Cloth. $6. Pp. 381. Philosophical Library, Inc., 15 E. 40th St., New York 16, 1959.

For all the years that man has been on earth, disease has been one of his chief enemies. Every culture has shown a lively interest in the healing arts. Elements of magical, demoniacal, and rule-of-thumb practices are common to all of them. The nature of the culture determines some attitudes. The Greeks, for instance, believed that illness marred the perfection of "whole man" and was thus a misfortune or a catastrophe. The Jews, while they shared the common experience of primitive peoples and borrowed much from their neighbors, gave their outlook on medicine a strongly religious tinge. Their monotheistic belief led them to think that sickness was sent by God as a punishment for sins. Castiglioni has pointed out that this reduced the number of superstitions about malignant demons, animistic concepts, and superstitious and magical practices. The Creator was compassionate, however, and, if approached through his priests with a contrite heart, was the source of healing. These attitudes influenced the development of Jewish medical and hygienic concepts.

From these beliefs sprang a tremendous body of regulations intended to insure the recovery from illness and the maintenance of bodily and spiritual health. It existed as an extensive code throughout the ages and regulated the hygiene of all the Jewish people. It was concerned with the control of epidemics through bathing and many other practices. The regulations, which have to do with ritual slaughter, foods which may not be eaten, circumcision, and purification after menstruation, are followed by the Orthodox Jew to this day. The author is concerned with the ethics of Jewish medical

practice as determined by Jewish sacred literature and tradition. He makes it clear that all medicine, while largely based on science, is and must remain an art with strong moral overtones. This the Jews brought about by way of their religious beliefs. No one should try to make medicine wholly scientific. The attempt would fail, anyway, but would nevertheless remove the properly strong overtones of compassion and high regard for the dignity of man's estate. These attempts can and do lead to the excesses of the so-called human experimental procedures, as seen, for example, in the Hitlerian regime. This interesting and scholarly treatise may be read with benefit and pleasure by all who are interested in the moral and ethical aspects of medicine.

Diabetes mellitus. III. Kongress der International Diabetes Federation Düsseldorf, 21.-25. Juli 1958: Proceedings, Verhandlungen, Comptes Rendus. Herausgegeben von Prof. Dr. K. Oberdisse, Direktor der II. Medizinischen Klinik und Poliklinik der Medizinischen Akademie Düsseldorf, und Priv.-Doz. Dr. K. Jahnke, Oberarzt der II. Medizinischen Klinik und Poliklinik der Medizinischen Akademie Düsseldorf. Cloth. 175 marks; $41.65. Pp. 799, with 225 illustrations. Georg Thieme Verlag, Herdweg 63, (14a) Stuttgart, West Germany; [Intercontinental Medical Book Corporation, 381 Fourth Ave., New York 16], 1959.

Participants in the Congress here reported represented 42 nations, and the contributions are printed in English, German, or French. The main subjects considered were (1) new theoretical knowledge of carbohydrate metabolism, (2) the diabetic angiopathy, (3) the oral treatment of diabetes mellitus, and (4) the problems presented by the diabetic child. Additional subjects presented at the round table included diabetes and pregnancy and methods of determining amounts of insulin, insulin antibodies, and insulin inhibitors in the blood. The discovery of diabetes in patients (the so-called detection drive), the care and aftercare of aged patients, and the demography of the diabetic were discussed in special sessions. The Banting Memorial Lecture entitled "Zur bedingten Gesundheit des Diabetikers" was delivered by Professor Gerhardt Katsch of Greifswald and emphasized the necessity of continuous medical control of diabetes.

More than 200 communications from 350 authors provided a comprehensive summary of the results of recent experimental and clinical investigations and of present opinions held by students of diabetes. The mechanism of the action of insulin was introduced by Dr. Rachmiel Levine of Chicago with a description of the experiments underlying the transport hypothesis. Further studies on glucose transport and its hormonal control were presented by Park and co-workers from the Vanderbilt University School of Medicine. A series of nine papers dealt with metabolism of carbohydrates and its relation to the metabolism of fat. Special emphasis was given to hepatic metabolism as influenced by insulin and to the marked sensitivity of adipose tissue to the action of insulin. The pathoanatomy and pathophysiology of the diabetic angiopathy were presented with special reference to the lipid metabolism, the lipoprotein, the possible role of renal corticoids, and the influence of heredity. The clinical aspects of the diabetic angiopathy involving the retina, kidneys, and surgical lesions of the extremities were discussed in numerous papers.

The oral treatment of diabetes was presented from the point of view of pharmacodynamics, chemistry, and morphology. Loubatières of Montpellier, France, believed that the arylsulfonamides might have a specific effect in insulin production, an opinion shared by few writers. Data indicating that the orally given drugs produce similar physiological effects to those observed with insulin are still scanty. The hypothesis that insulin release from the pancreas is the mode of action of these drugs still lacks satisfactory proof. The effects of such drugs in juvenile patients are slight unless the child is in a period of diabetic remission.

The use of tolbutamide in 9,168 patients treated in the United States was analyzed by C. J. O'Donovan. Of these, 58% were female, less than 1% were under 20 years of age at the time of treatment, and only 5% were between 20 and 40 years of age. In contrast to the usual statement that 80% of adult diabetics are overweight, in this series 12% were asthenic, 45% were of medium build, and only 30% were heavy or obese. This figure agrees with the estimated incidence of obesity in the adult population of the United States. The body habitus is not a major determinant of response to therapy. The percentages of satisfactory control were practically identical in those patients who were of medium build and those who were obese. In this series, 14% has been on no former regimen of therapy before treatment was started with tolbutamide, since many were only recently discovered to be diabetics; 23% had been on diet alone before oral treatment; and 61.7% had had some previous insulin treatment. The highest percentages of success in treatment were in the group who had had no previous treatment with insulin.

R. H. Williams and co-workers studied not only tolbutamide and chlorpropamide but also certain biguanides, which had been shown to cause a significant decrease in hyperglycemia. Phenethylbiguanide inhibits certain oxidative enzymes. The anoxia which is produced leads to a decrease in gluconeogenesis and to an increase in the uptake of glucose by peripheral tissue. These factors lower the blood sugar level, but presumably more than these effects are required to correct the diabetic state.

Data indicating the effect of tolbutamide on various enzymatic processes in the liver were presented by Wallenfels and Creutzfeldt of Freiburg. The studies of Pfeiffer and others, demonstrating an increase in insulin output in the pancreatic vein after intravenous infusion of tolbutamide, whereas the opposite effect was obtained after injection into the femoral vein, were of special interest. Large series of patients treated with the orally given substitutes for insulin were reported by Boulin and Rambert of Paris, Marble of Boston, Bertram of Hamburg, and others.

The psychological problem encountered in the management of the severe diabetes in children were presented by Bruch of New York and Leonhardt of Karlsburg. Clinical experience stressed the difficulties of rehabilitation of severely affected children. A panel of contributors brought to the fore the problems encountered in pregnant diabetic women. Studies of adrenocortical function, the uterine blood flow, and the effects of vascular disease on the course and outcome of pregnancy in diabetics were stressed.

Methods of insulin assay were presented and the adipose tissue method of Renold was especially stressed. The determination of serum insulin levels by the rat diaphragm method gives comparable results, but apparently the more recent method, with use of adipose tissue, is more reliable. Insulin antibodies and insulin inhibitors are being studied in Cambridge, Seattle, and London. A factor in the alpha-1 globulin fraction of plasma, found in the plasma of patients with diabetic acidosis, frequently disappears after the institution of insulin therapy. It is a protein and is inactivated by chymotrypsin. In diabetic or nondiabetic subjects, after insulin injections have been given for several weeks, antibodies which inhibit the fixation of insulin to the tissues and other factors in the problem of insulin resistance were presented. The consensus of workers in the field was that intensive efforts with new techniques should add knowledge of great practical importance. This volume, replete with data, is recommended for all physicians interested in the study and treatment of diabetes.

Chemistry of Pancreatic Diseases. By Harris Busch, M.D., Ph.D., Associate Professor of Pharmacology, Department of Pharmacology, University of Illinois College of Medicine, Chicago. Publication no. 377, American Lecture Series, monograph in American Lectures in Living Chemistry. Edited by I. Newton Kugelmass, M.D., Ph.D., Sc.D. Cloth. $5.25. Pp. 160, with 22 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1959.

This book attempts to integrate the clinical, physiological, and biochemical knowledge of pancreatic diseases. This is a vast undertaking, and the author has met with varying degrees of success in his efforts. The exposition on exocrine pancreatic function is complete and excellently presented. The references to the recent applications of electron microscopy and ultracentrifugation techniques indicate the comprehensiveness of this section, but the discussion of endocrine pancreatic function is largely concerned with the details of insulin and carbohydrate metabolism and is somewhat cursory. The clinical section, particularly the part on the management of diabetes mellitus, is overly brief, and such interesting entities as the Zollinger-Ellison syndrome and hemochromatosis are not mentioned. In the concluding discussion, on neoplastic diseases of the pancreas, clinical deficiencies are evident from the omissions of the important diagnostic techniques of duodenal intubation and cytological and biochemical studies of the pancreatic fluid before and after stimulation. The material is well organized and presented clearly and the bibliography is impressive, but the inadequancies mentioned make it difficult to recommend the book wholeheartedly to the biochemist, researcher, clinician, or medical student, although each should find the volume valuable in some areas.

Gripe Asiatica. By Dr. Manoel Bruno-Lobo, in Portuguese, by the Institute of Microbiology of the University of Brazil. Rio de Janeiro, 1958, pp. 123. Price not stated.

Gripe asiática. Por Manoel Bruno-Lobo. [Trabalho apresentado em 30 de agôsto de 1958 à Comissão Julgadora do concurso "Revista Médica do IPASE" e que, merecendo o Prêmio de 1958, foi editado por essa Instituição. A parte experimental dêste trabalho foi realizada no Instituto de microbiologia da Universidade do Brasil, com a colaboração de J. Travassos, Gilda G. Bruno-Lobo e Júlia V. Vasconcellos, técnicos da Divisão de vírus, sob a orientação científica do Professor Paulo de Góes.] Paper. Pp. 123, with illustrations. Instituto de microbiologia, Universidade do Brasil, Rio de Janiero, Brazil, 1958.

This book, a prize winner in a contest sponsored by the *Medical Journal of the Institute of Pension and Retirement for State Employees*, is a study in five parts. Part 1 deals with generalities regarding Asian influenza and the role of the World Health Organization during the 1957 epidemic. Part 2 concerns the history and epidemiology of the epidemic which began in China and spread to the entire world. The disease entered Brazil through the southern border in the autumn of 1957. Part 3 deals with the laboratory investigations. Parts 4 and 5 constitute the original contributions in this work, which are the experimental, virological and serologic studies made at the Institute of Microbiology.

The material for the immunogenic study of the influenza outbreak in Rio de Janeiro, in 1957, consisted of paired serums, one in the acute and one in the convalescent phase. They came from patients at the Institute Benjamin Constant, students and recruits at the School of Aeronautics, patients at the Hospital for State Employees, private patients, and volunteer donors at the City Blood Bank. Serums were obtained also from subjects in three small communities in the state of Pernambuco, in the northeastern part of Brazil, where the epidemic had not yet spread.

The findings in each group were compared with those obtained by researchers in other parts of the world. In one of the three small communities the serum was obtained from 31 subjects prior to vaccination and 20, 35, and 50 days after vaccination. Of this sample 22% presented neutralizing antibodies for the A/Formosa-313/57 type before they were vaccinated. This is lower than the percentage of the total sample composed by the three small communities (29%) but higher than the values found by other researchers. This fact led to the hypothesis that some persons had already harbored a latent form of viral infection. Twenty days after vaccination the percentage of subjects with neutralizing antibodies reached 63%. The effectiveness of the vaccine may be evaluated in terms of the difference between the two degrees of immunization, *about 41%, which was in accordance with findings* of other researchers. There is an intensive bibliography. The book is a valuable contribution to our knowledge of Asian influenza.

Proceedings of the Research Conference on Problems of Alcohol and Alcoholism, Held at Washington, D. C., 25-26 October 1958. Sponsored by North American Association of Alcoholism Programs, under grant from National Institute of Mental Health. Proceedings editor: Ebbe Curtis Hoff. Special reprint from Quarterly Journal of Studies on Alcohol, vol. 20, no. 3, September 1959. Paper. Gratis to libraries and institutions. Pp. 415-672, with illustrations. National Institute of Mental Health, Community Services Branch, Bethesda, Md., 1959.

This book consists of 25 papers on different aspects of the problems of alcoholism. The introductory article, written by E. C. Hoff, outlines the purposes of the conference with general explanatory remarks about the proceedings. The approaches to the problem of alcoholism include the physiological, sociological, medical, psychiatric, and experimental. Biochemical and nutritional studies are also presented. Several articles describe the experiences of the staff of the Alcoholism Clinic of the New York State University College of Medicine, in Brooklyn, N. Y. Another paper is devoted to the study of alcoholics in a New England prison. Some of the reports are evaluations of drugs used in the treatment of the alcoholic patient. One paper explains the experimental use of d-lysergic acid diethylamide. Statistical reports compare the mortality among treated alcoholics and characteristics of alcoholics as related to prediction of therapeutic outcome. Comparison between alcoholics and nonalcoholics in traffic accidents is the subject of another paper.

Sociologic studies include the measuring of knowledge about alcoholism in a community, teenage drinking as group behavior, and the comprehensive approach to the problem of alcoholism. While this book can be of great value to any physician who reads it, more will be gleaned from it by the person who has had experience in the diagnosis, treatment, and general care of alcoholic patients. The general practitioner can gain much from the perusal of the sociologic papers. Some of the more technical papers dealing with the experimental approach and the biochemical studies should be of greater value to those who have specialized in the field of alcoholism. Sociologists should find many of the papers extremely interesting.

A few of the papers should be of particular interest to the clinician, since they deal with the direct contact of the physician with the alcoholic patient, but since most of these experiences are with patients in a clinic, it would be of more interest to people employed in such clinics than to private practitioners. There is, however, enough to be gained from these papers to help the private practicing physician in gaining insight into the problem of dealing with alcoholic patients. This can be of much value to him in his practice, not only in the treatment of patients who come to him suffering from the illness but also in the early detection of cases which have not become sufficiently advanced for the patient to seek help. This can be helpful in case finding. Although this book is primarily for the person who specializes in the field of alcohol and alcoholism, the nonspecialist can gain a great deal from a careful study of its contents.

1957 Inventory: Municipal and Industrial Waste Facilities. Volumes 1-9. U. S. Department of Health, Education, and Welfare, Public Health Service, Bureau of State Services, Division of Sanitary Engineering Services, Water Supply and Water Pollution Control Program, Washington, D. C. Public Health Service publication no. 622. [Cooperative state-federal report. Published by state region.] Paper. 65 cents; $1.75; $1; $1; $1.75; $1.25; $1; 60 cents; $1.25. Pp. 129; 362; 196; 160; 339; 241; 180; 109; 267. Superintendent of Documents, Govern. Print. Off., Washington 25, D. C., 1959.

These nine volumes constitute a report on community and industrial waste disposal. They consist exclusively of tables that present information about selected or specified communities, including tables for each of the states. There appears to be no attempt to obtain either city or county information which could be used to make comparisons. The format of the tables is confusing, since as many as three different items are placed in one column. For example, the first column is titled "Community, Sewer or Sanitary District, Institution or Industry," and extends across two columns of information. The next column includes the 1950 population, the 1957 estimated population, and the number of plant employees. Three entirely different items are placed in one column, making it difficult to distinguish the figures from each other in this one column or to know to what a figure refers. These volumes should prove helpful to municipal and state regulatory officials concerned with municipal and industrial waste problems and water pollution control activities.

QUESTIONS AND ANSWERS

MIGRAINE HEADACHES

To the Editor:—*A 48-year-old patient has suffered from headaches since he was 21 years old. He has been seen by numerous doctors and consultants, and the diagnosis consistently has been histamine-type headache, localizing in the right temporal blood vessels. He is confused by a variety of statements concerning the efficacy or uselessness of the following procedures (some of which have been tried): (1) desensitization with intravenously given histamine, (2) treatment by subcutaneous administration of a histamine-azoprotein complex, (3) treatment with repeated small doses of x-ray (apparently based on the same principles as treatment of postherpetic neuralgia), and (4) a number of ancillary and nonspecific types of therapy. What are the therapeutic potentialities of one or more of the three procedures enumerated?*

T. H. Klunder, M.D., Hatch, N. Mex.

Answer.—Paroxysmal attacks of cluster headaches have been well documented during the past 90 years under a variety of clinical entities and eponyms. Most theories state that they are periodic episodes of local dilatation in extracranial vessels, mainly those supplied by the branches of the external carotid arteries (i.e., migraine).

The subcutaneous and intravenous administration of histamine has been recommended by Horton (for suggested dosage and plan of histamine therapy see Horton, B. T.: Histaminic Cephalgia, Horton's Headache or Syndrome: Provocative Tests, *Triangle* 3:66 [June] 1957) and recently he has advocated the use of whole cortical extract, ACTH, or cortisone (100 mg. intravenously daily), three or four days or longer before desensitization. Most clinicians who have experience with this syndrome have found histamine quite ineffective. There is no adequate prophylactic treatment other than reduction of stress factors. The intensity of the attacks can be modified with nonspecific chemotherapy, nonspecific medical attention, resolution of personal problems, emotional support, and rest. Ergotamine tartrate is effective for relief of symptoms.

OXYGEN FOR ATHLETES

To the Editor:—*Of what value is oxygen in relieving the dyspnea caused in athletes by physical exertion? Would administration of oxygen restore strength to an exhausted athlete?*

A. C. Scott, M.D., Stillwater, Okla.

Answer.—The present fad of administering oxygen to hasten recovery of athletes after physical exertion is not based on sound principles of physiology. Experimental evidence on the subject is conflicting, and, because of the effects of practice and warmup periods, studies are difficult to control. The body does not store up oxygen, and, since the effect of oxygen-inhalation wears off in about three minutes, no benefits can be anticipated from administration of oxygen in activities involving prolonged exertion. Inhalation of oxygen by athletes immediately before participation in events such as short track sprints and short swimming races (in which breath-holding is a factor) may be of limited value, but these benefits probably can be obtained in the same degree by forced deep-breathing of ordinary air.

A review of scientific studies on the influence of oxygen administration to athletes was carried out in 1953, and the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association concluded: "Valid scientific evidence in support of the value of administration of oxygen in athletic competition is lacking. It is unwise and dangerous to encourage the athlete to exert himself beyond the limits he has learned to respect from instinct and experience. The anticipation of help from oxygen inhalations increases this possibility. The Joint Committee therefore strongly recommends that the use of oxygen for such purposes be disapproved." In 1955, the Committee reviewed the above statement and reaffirmed its stand.

CONTROL OF CEREBRAL EDEMA

To the Editor:—*What treatment will reduce the intracranial edema in a patient with concussion or fracture of the skull who does not have any signs and symptoms of intracranial pressure due to localized hematoma?*

M.D., New York.

Answer.—The localized areas of cerebral edema which occur after trauma to the head are believed to be due to the increased permeability of capillaries. In most patients this condition is reversible and clears in a few days, but in children it can

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

progress to liquefaction necrosis and may cause death. A localized area of this type of edema is, in its relation to the brain, an intracerebral mass. Therefore, its appearance may simulate contusion, hematoma, abscess, or neoplasm in a pneumoventriculogram or cerebral angiogram.

Theoretically, the intravenous administration of hypertonic solutions, if given early in the treatment, should decrease cerebral edema. At present urea is the preferred agent. Although the use of all such solutions carries the risk of secondary increase in cerebral edema when the solute leaves the blood stream through damaged capillaries and enters the swollen cerebral tissue, urea minimizes this hazard, and its use is, therefore, definitely helpful immediately before craniotomy.

Another major risk of systemic dehydration is the presence in the patient of unrecognized intracranial hemorrhage; such areas of hemorrhage may increase with the relative decrease of brain volume. Systemic dehydration may also cause or prolong fever.

The head and chest of patients with traumatic cerebral edema should be elevated to lower intracranial venous pressure. Adequate respiratory function, total protein content, electrolyte and water balance, and hemoglobin level of the blood must be maintained in the patient. Mercurial diuretics, chlorothiazide and its derivatives, acetazolamide, and steroids have not been established as beneficial therapeutic agents for the management of patients with traumatic cerebral edema.

WRITING PROBLEMS OF LEFT-HANDED CHILDREN

To THE EDITOR:—*A 5-year-old girl who is left-handed writes from right to left and also produces an upside-down mirror image. I would appreciate suggestions about the diagnosis and treatment of this patient.*

John M. Bell, M.D., Marinette, Wis.

ANSWER.—When a child is naturally left-handed, his speech center usually develops in the opposite cerebral hemisphere, in conformity with the economy or symmetry of cerebral organization. An attempt to force the child to change the hand used in writing may lead to functional confusion in the brain and an attempt to switch the speech center, which may result in a stammer.

Images of objects observed by the right part of the visual field are transmitted by the lens to the left side of each retina. The impulses go from the retina through the left optic tract to the left visual cortex, where they easily transfer to the left brain center, i. e., to the site of origin of impulses for reflex protective movements of the right arm.

The mental image of objects in the right visual field is related to the right hand and to the right eye, and the act of writing is a hand movement directed toward the right visual field and best seen by the right eye. The left-handed child's attempt to write makes him move the pencil toward the left side and upside down. (Orton: *A. M. A. Arch. Opth.* 30:707 [Dec.] 1943). Adults with right homonymous hemianopsia have to read into a blind area, which is difficult even when they have 20/20 vision. Some of them find it easier to read upside down, in which case they read toward the seeing part of the visual field.

A child should be urged gently to change from left-handedness to right-handedness; if he stubbornly refuses to do so, special teaching procedures must be applied to correct his mirror writing and reading.

HIGH FREQUENCY SOUNDS

To THE EDITOR:—*Where can I obtain information that would relate the deleterious effect of high-pitched sounds on rats to the pathogenesis of convulsive seizures that are caused by such sounds?* *Vito Vighi, M.D., Ottawa, Ill.*

ANSWER.—Because of anatomic differences in the various animals used for such experiments, nearly all recent histopathological studies on "acoustic injury" to the ear have been performed on guinea pigs and, apparently, none on rats (Davis: *Physiol. Rev.* 37:1 [Jan.] 1957; on submicroscopic damage, see Spoendlin: *Pract. oto-rhino-laryng.* 20:197 [July-Sept.] 1958). The highest pitch used in these experiments with guinea pigs was about 6,000 cps, which is high pitch for man but not for the rat. The most audible pitch for rats is apparently about 40,000 cps (Gould and Morgan, *Science* 94:168 [Aug. 15] 1941, and the rat produces sounds composed of up to at least 80,000 cps (Anderson, *Science* 119:808 [June 4] 1955).

VERTIGO AND AURICULAR FIBRILLATION IN THE GERIATRIC PATIENT

To THE EDITOR:—*What is the treatment for elderly patients who (1) faint when they make a sudden change in posture and (2) have auricular fibrillation?* *M.D., Pennsylvania.*

ANSWER.—Positional "dizziness" is a frequent complaint of elderly persons and is considered an accompaniment of cerebral atherosclerosis due to the inability of the cerebral circulation to adapt quickly enough to a change in position. Vertigo is precipitated by the movement of the body and not its changed position.

Elderly persons are disabled by many pathological processes which contribute to inefficient responses of the body. Treatment is directed toward a decrease in the severity of the patient's symptoms and the best possible restoration of his health. Despite the manufacturers' claims of their therapeutic efficacy, new antimotion drugs have little effect on this type of vertigo. Ephedrine, 25 to 50 mg. taken three times daily, seems to be most effective in decreasing the frequency and severity of the faintness. The patient should be instructed not to move suddenly, and the physician must continue to reassure the patient that the difficulty is not serious.

Rapid auricular fibrillation must be controlled with administration of digitalis or a digitalis-like drug. Elderly patients who develop a slow auricular fibrillation that progresses slowly do not require digitalis therapy. Many physicians feel that conversion to a normal sinus rhythm should be attempted, while others are satisfied with a controlled rate, with or without administration of digitalis. Generally, patients with controlled fibrillation in the age group described who feel and do well need not be treated. Patients who are disturbed by the palpitations and thus are difficult to control, or who are heart-conscious and whose heart rhythm is easily converted and maintained, should be treated, however.

TEST FOR POISONOUS MUSHROOMS

To the Editor:—*Some persons who think they can tell nonpoisonous from poisonous mushrooms have asked if there is some simple chemical test that can be used to indicate the difference. Is there any such test?*

Joseph L. Mangiardi, M.D., Garden City, N. Y.

Answer.—Analytic methods for the detection and quantitative estimation of one of the toxic principles (muscarine) in mushrooms are available. The practical use of these methods is limited by their complexity, and, more important, the varieties of toxic mushrooms contain different toxic principles. There is no simple test which will detect all of the poisonous principles which may be found in mushrooms.

CERVICAL JOINT STRAIN

To the Editor:—*A 36-year-old man, whose automobile was struck from behind, suffered acute muscle strain of the cervical vertebral joints. Three days later he noted a hearing loss, and audiometric tests showed that he had a 20-db hearing loss in the low tones and one of 40 db in the high tones in each ear. Could there be any relationship between acute cervical joint strain and hearing loss?*

Ephraim L. Manning, M.D., Davenport, Iowa.

Answer.—It is extremely difficult to answer this question with the incomplete amount of information given. We do not know what this patient's hearing by bone conduction is, but, in general, this hearing loss suggests a bilateral perceptive deafness of slight degree. If this were due to a hydrops of both cochlear labyrinths, adequate treatment for this disease should cause some change in the audiometric picture, since the degree of deafness is slight, but it is unlikely that the involvement would be bilateral. A bilateral perceptive deafness of equal degree involving both cochlear nerves would not have any relation to the type of injury this patient sustained.

PARENTAL CONSENT

To the Editor:—*We have a difference of opinion about the necessity of parental permission for the performance of a pelvic examination on a young girl. The nurses at two colleges in this community have been told that no patient under 21 years of age should have a pelvic examination without written permission from her parents. The administrative policy in the two colleges is to refer a girl with a pelvic complaint to us for discussion and evaluation of her problem and, if an examination is needed, to obtain the parents' permission by letter or telephone. This seems a waste of time and money, and it is my impression that 18 years is the legal age of consent for women in Illinois.*

Mary Louise Newman, M.D., Jacksonville, Ill.

Answer.—Young girls attain legal adult status at the age of 18 years in Illinois. A girl mature enough to attend college is considered able to make her own decision about having a pelvic examination, even though she may be under 18 years of age. The physician should not hesitate to perform the examination if a teen-ager has profuse bleeding, severe abdominal pain, or other signs of symptoms which require investigation and treatment. If a college girl consents to a pelvic examination, it can be performed, when necessary, to ascertain that her pelvic organs are normal. If a vaginal examination appears to be too uncomfortable for the patient, a rectal examination often will suffice. It is important that a male physician remember to have his nurse or secretary in the room during the course of the examination.

TRANSAMINASE TEST

To the Editor:—*If serum transaminase levels are used as a prognostic criterion, when should a patient convalescing from viral hepatitis be allowed to be ambulant?*

William E. Arbuckle, M.D., Indianapolis.

Answer.—The serum glutamic oxalacetic transaminase (SGO-T) level is one of the best quantitative measures of acute liver injury, but it must be remembered that, when liver failure develops (with precoma or coma), the levels usually fall. The test provides a fair index of the patient's ability to commence or increase ambulation, but individual variations preclude the possibility of setting up standard levels. Excessive exertion by the patient can cause a sharp rise in his transaminase level; therefore, it cannot be stated whether this test would be more significant than others. If results of liver function tests show deterioration of the patient's condition with a given amount of physical exertion, it is probable that the inflammatory reaction in the liver has increased. The transaminase level should be below 100 units before the patient is allowed unrestricted ambulation.

FACIAL MUSCLE TIC

To the Editor:—*A 62-year-old man has a tic of the muscles of expression on the right side of his face. He has had it since 1941, and it has gradually become worse. The tic is most noticeable and severe when the patient suffers emotional stress. He has consulted a neurosurgeon who, because the patient has poor vision in the left eye, advised against alcohol injections to interrupt the nervous pathways of the tic. Interruption of the nerve tracts might interfere with the blink reflex in the right eye, which would diminish the total visual acuity. Since the center of his tic is in the musculature of expression around the zygomatic arch, or somewhat below, and spreads superiorly and inferiorly to involve the platysma on that side, would an alcohol injection of the maxillary branch only of the trigeminal nerve be of benefit to this patient? Past medical therapy has consisted of general sedation with barbiturates, tranquilizers, mephenesin, nicotinic acid, thiamine hydrochloride, vitamin B_{12}, and procaine hydrochloride infusion to the trigger point of the tic. None of these measures has been successful.*

George M. Wolverton, M.D., Clarksville, Ind.

Answer.—The problem of the patient who is suffering from a right facial tic is fraught with therapeutic difficulties. The right seventh nerve is affected, and alcohol injection is both technically difficult and contraindicated because of poor vision in the right eye. Since the patient has had neurosurgical consultation, it would be best not to attempt further treatment.

EYE IRRITATIONS AND ANESTHETIC AGENTS

To the Editor:—*As an anesthesiologist I am concerned with the complication called "ether eye" after administration of ether anesthesia. Information about the prognosis of patients with this complaint will be appreciated.*

Stephen H. Mazur, M.D., Maplewood, N. J.

Answer.—Ether eye is a keratoconjunctivitis or simple conjunctivitis that occurs in a patient after the administration of open-drop ether anesthesia, during which liquid ether may or may not have come into contact with the eye. It is usually a self-limiting condition which seldom requires treatment other than application of an anesthetic ophthalmic ointment, such as tetracaine hydrochloride, for the local relief of pain. The patient's eye should be covered with a patch, in the more severe cases. Permanent sequelae, such as corneal opacities or iritis, occasionally occur; when they do, the etiological question is whether or not additional trauma to the eye occurred during administration of the anesthesia or during the postoperative recovery of the patient. If ether vapor is used as the anesthetic agent, a generalized vasodilation of blood vessels in the conjunctival membranes can occur.

TREATMENT OF BURSITIS

To the Editor:—*Is there a therapeutic agent, administered by hypodermic injection, that will cure a patient of an olecranon bursitis?*

William S. Levy, M.D., Woonsocket, R. I.

Answer.—Intrainjection of hydrocortisone, or similar derivatives, has proved of considerable value in relieving olecranon bursitis, with or without a collection of fluid, in most patients. One method is to dilute 1 to 1.5 cc. (25 mg. per cubic centimeter) of hydrocortisone in 4 or 5 cc. of a local anesthetic and inject the mixture into the bursal space after as much as possible of the bursal fluid has been drained. It usually is wise to apply pressure by means of a rubber sponge and an Ace bandage for a period of two or three days. This procedure can be repeated in one to two weeks, if necessary. For the patient with a severe chronic olecranon bursitis this procedure may not be adequate and surgical excision of the bursa may have to be performed.

REMOVAL OF SUPERNUMERARY BREAST

To the Editor:—*Should supernumerary mammary glands be excised as a preventive measure against development of a breast cancer?*

La Salle Mondor, M.D.,
Grand 'Mere, Quebec, Canada.

Answer.—Supernumerary mammary glands, a form of polymastia, occur frequently in women and may be associated with polythelia, or supernumerary nipples, which are usually located along the milk line on one side or both sides. The prophylactic removal of supernumerary mammary glands is not indicated unless the presence of a tumor can be demonstrated. The glands in the breast may be affected by the menstrual cycle and may cause swelling and tenderness, which usually regresses after menstruation, in the axilla. There is no more reason to remove such tissue as a prophylaxis against cancer than there is to remove normal mammary glands.

Administration vs. White Fleet . .
Hearings on Automobile Exhaust . .

PRESIDENT DIRECTS STUDY OF ADDITIVES

President Eisenhower ordered three federal agencies to make reports to him on the use of chemical additives in food, an issue that has stirred considerable controversy since last autumn when the government banned some lots of cranberries.

In handing down the order, the White House made clear that the study "has no relation to the enforcement of the appropriate laws" by the Department of Health, Education, and Welfare. "These laws were enacted for the protection of the consumers of the nation and will continue to be strictly enforced," the statement said.

The Food and Drug Administration, the Agriculture Department, and President Eisenhower's Science Advisory Committee were assigned to report on the subject of chemical additives that are used to store, flavor, and color foods.

President Eisenhower, according to White House Press Secretary James Hagerty, "wants to find out the various problems in the whole field and asked these scientists to make this investigation."

HEW Secretary Arthur S. Flemming said that he had no intention of suspending enforcement of the chemical additives laws pending results of the study.

The study should be completed in the near future, said Hagerty. The administration has asked Congress to modify present statutes to allow tolerances on color additives that may cause injury when fed in large quantities to test animals but which would not be harmful in minute amounts. Under present law, tolerances are not allowed. However, the administration has urged retention in the color bill of a ban against tolerances for chemical additives that cause cancer.

The latter recommendation has drawn the fire of the pharmaceutical industry which contends it is too rigid. In testimony before the House Commerce Committee, Dr. Thomas P. Carney, testifying for the Pharmaceutical Manufacturers Association, said he did not believe that it was the intent of Congress to prevent the use of any chemicals that "would be safe when used in regulated amounts and under proper conditions."

Mr Flemming, however, has announced that he will ask Congress to relax the anticancer provision of the law so as to allow the use of additives that may cause cancer in test animals provided there is no residual amount of the material in the food as eaten by consumers. This would permit continued use of the hormone-like chemical stilbestrol in feed for beef cattle.

DEATHS FROM INFLUENZA AND PNEUMONIA RISE

The Public Health Service reported sharp increases in deaths from influenza and pneumonia. During the first five weeks of this year, 4,033 such deaths were reported by the 108 large cities that supply weekly death data to the government. The total was a 44% increase from the 2,798 deaths for the same period in 1959 and a 20% increase from the 3,357 reported in the same period of 1958.

Deaths from all causes in large cities this year are also more numerous than they were during the same period of the two previous years, PHS said.

Commenting on the high number of deaths from influenza and pneumonia, Dr. Burney said,

"The figures seem to bear out clinical impressions of some physicians that they are encountering a more than normal amount of pneumonia this year. Reports from some areas that absenteeism is higher in industrial populations than in school populations, as well as some reports that the majority of pneumonia and influenza deaths are occurring in the over-65 age group, suggest that the respiratory infections this year are attacking adults more frequently than children."

Almost half of the states confirmed the diagnosis of Asian-type influenza in one or more areas, but their reports showed a pattern of localized outbreaks rather than the progressive and complete involvement of wide areas that characterized the 1957-58 Asian influenza epidemic.

After outbreaks occur, vaccination cannot be expected to have much value in controlling influenza, according to Dr. Burney. "However, with proper medical and nursing care, many of its serious complications can be avoided," he said.

A. M. A. BACKS DESIGNATED PHYSICIANS FOR PILOT CHECKS

The American Medical Association urged the Federal Aviation Agency to require that only specially designated physicians be allowed to examine private and student pilots for license qualifications. Testifying at an agency hearing on this proposal, Dr. Hugh H. Hussey, member of the A. M. A.'s Board of Trustees, noted that the A. M. A House of Delegates has approved a resolution stating, in part, "These examinations should be made by those physicians who are qualified to make aeronautical-type examinations, so that the best interests of the public, and especially of those who operate or utilize aircraft, may be served."

(Continued on page 26)

"In order that the mental and physical fitness of an air crew member may be safely determined, the examiner must be a doctor of medicine with special knowledge and proficiency in certain techniques," according to the report made to the House of Delegates.

At present, designated medical examiners are required for physical examinations of commercial pilots. The FAA has proposed extending this to all pilots.

Asked if the A. M. A.'s position ran counter to the principle of free choice of physician, Dr. Hussey replied, "Let me assure you that the A. M. A. still jealously guards the principle of freedom of choice where this refers to medical care in the broad sense. The type of examination that we are talking about here is not really in the area of medical care generally. This would be analogous in some respects to the activities of a health officer, for example."

Supporting the A. M. A.'s stand was Dr. Neal Baxter, president of the Civil Aviation Medical Association, who declared that even a well-trained physician could not be expected to assess pilots' physical qualifications without specific instruction.

A spokesman for the Flying Physicians' Association criticized some aspects of the proposal but indicated the organization supported the principle.

Dr. Malcolm Phelps of the American Academy of General Practice took issue with the proposal, declaring that family physicians are more familiar with their patients and better qualified to examine persons whose case histories are familiar.

Also opposing the plan were representatives of the Aircraft Owners and Pilots Association, National Pilots Association, and Utility Airplane Council of Aerospace.

However, Dr. Ludwig Lederer of Aerospace Medical Association said the proposal would not interfere with the principle of free choice of physician and recommended that the number of qualified examiners be increased.

The FFA proposal is part of a wide new safety program instituted by the new federal agency. A Senate aviation subcommittee headed by Sen. Mike Monroney (D., Okla.) has been holding hearings on the new rules and the general subject of air safety.

ADMINISTRATION OPPOSES DISASTER RELIEF FLEET

The administration told Congress that the proposal for a "great white fleet" of naval vessels to bring medical and other relief to foreign countries "does not appear to be practical."

In a letter to the House Armed Services Committee, the Navy Department said its "experience in disaster relief is that one small group of ships could not be expected to render timely and effective aid in any significant number of natural disasters."

Proposals for a great white fleet have been introduced by many lawmakers since last year. Under them, surplus naval vessels would be restored to working order and would tour the world furnishing food and medical assistance to nations needing them.

The Navy said the concept was "laudable," but that it would "not warrant the large expenditures of funds which would be required." As now established, with bases spread around the globe, the Navy is in a good position to render emergency relief without setting up a separate fleet, according to the letter.

Project Hope, the soon-to-be dispatched hospital ship financed by private funds, may be used as an aid in determining the potential value of a great white fleet, said the Navy, in the letter that was cleared by the budget bureau.

The administration's position appeared to weigh heavily against chances of Congress passing such legislation this year.

HEARINGS ON AUTOMOBILE EXHAUST SLATED

A House commerce subcommittee scheduled hearings on air pollution, as two lawmakers called for installation of smog filters on all automobiles. Subcommittee Chairman Kenneth Roberts (D., Ala.) called public health officers and automobile industry spokesmen to testify. He said that automobile-caused air pollution is a problem of all metropolitan areas.

Meanwhile, Sen. Wayne Morse (D., Ore.) contended that auto makers could install exhaust devices for less than $1 a car, and he urged that they be made standard equipment. Representative Roberts said this was one of the major questions he would put to the industry witnesses.

MISCELLANY

The Senate passed and sent to the White House legislation almost doubling federal funds for combating water pollution. The bill would increase to 900 million dollars the present 500-million-dollar ceiling on federal grants to states and localities for construction of sewage plants and other steps to reduce water pollution. The authorization is over a 10-year period. The administration had urged a cutback in the federal share of the program on the grounds that it is largely a community responsibility.

A House veterans' affairs subcommittee held one week of hearings on the adequacy of funds to provide for maintenance, repair, and construction of Veterans Administration facilities. Directors of VA hospitals and spokesmen for veterans' organizations were the principal witnesses. Many urged increases in appropriations. The hearing was part of the subcommittee's annual review of such matters.

A House judiciary subcommittee planned hearings in March on various proposals for a White House Conference on Narcotics.

The Children's Bureau of the Social Security Administration issued a new pamphlet to encourage and instruct parents of children handicapped by the absence of an arm or leg. The document, "The Child with a Missing Arm or Leg," may be obtained from the Superintendent of Documents, Government Printing Office, Washington 25, D. C., for 25 cents a copy.

The 350-bed Public Health Service Hospital for tuberculosis patients at Manhattan Beach, Brooklyn, N. Y., will be closed June 15 because of the decreasing number of patients.

"SUNNY SIDE UP"

Specific effectiveness
in morning sickness
with

MORNIDINE®

for

- **Prevention of nausea and vomiting**
- **Selective action on the emetic center**
- **"Excellent" or "good" relief**
- **Little or no drowsiness**

Mornidine (brand of pipamazine), another achievement of Searle Research, provides selective action on the vomiting center with very little drowsiness. Mornidine is extremely effective in morning sickness. In 145 pregnant patients, 91 per cent had "excellent" or "good" relief from nausea and vomiting.

Doses of 5 mg. at intervals of six to eight hours provide effective relief all day. Suggestion: first tablet to be taken upon awakening.

For patients unable to retain oral medication when first seen, Mornidine may be administered intramuscularly in doses of 5 mg. (1 cc.).

NEUROSURGICAL TREATMENT OF SPONTANEOUS INTRACRANIAL HEMORRHAGE

IMPORTANCE OF DIFFERENTIAL DIAGNOSIS IN "CEREBRAL APOPLEXY" AND EVALUATION OF LONG-TERM POSTOPERATIVE RESULTS

Michael Scott, M.D., Philadelphia

The appropriateness of anticoagulants in treatment of real or apparent cerebral apoplexy depends on the differential diagnosis between hemorrhage and occlusion. Because recent animal experiments show that anticoagulants increase bleeding into infarcts produced by occluding blood vessels, the author questions the use of anticoagulants in any primary cerebral vascular accident. A follow-up study was made in 30 patients in whom certain indications had led to exploratory trephination and ultimately to verification of the diagnosis of hemorrhage. In two patients the hemorrhage was into a tumor. Nine others died in the hospital, and 19 who were discharged from the hospital after operation were available for follow-up study. The history of a hypertensive woman aged 25 years is given in detail to illustrate the clinical course of a hemorrhage into the internal capsule and the resumption of occupational activity after operation despite residual paralyses. Hemorrhages into the internal capsule were more serious than hemorrhages into the temporal lobe, but in both situations lives were saved by prompt neurosurgical intervention.

CEREBROVASCULAR disease is the third most common cause of death in the United States. In 1956 there were 177,845 reported deaths from vascular diseases of the central nervous system.[1] This is over four times the number of persons that died from motor vehicle accidents and six times the death rate from diabetes during that year.[1] It is estimated that there are over 1,800,000 victims of cerebrovascular disease in the United States today.[2]

The justified pessimism which existed 20 years ago concerning the success of medical or surgical therapy in cerebrovascular disease has been modified during the past 10 years by reports of an increasing number of patients whose lives have been saved and in whom neurological disability has been lessened by more accurate diagnosis, selective medical and neurosurgical therapy, and use of rehabilitation measures. The relatively recent acceptance of cerebral angiography as an important aid in the differential diagnosis of "stroke problems" has revealed an unsuspected incidence of congenital cerebral berry aneurysms, arteriovenous malformations, and occlusive disease of the arteries of the neck and brain as causes for this condition.[3]

Although this paper does not primarily deal with cerebrovascular occlusive disease, the recent popularization of the use of anticoagulants in stroke problems makes it the duty of writers on this subject to stress the crucial importance of differentiation of

Read before the Section on Nervous and Mental Diseases at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 9, 1959.

cerebral vascular occlusive disease from cerebral hemorrhage or even brain tumor; I shall discuss this problem later.

In 1951, I[4] reported before this Section on my experience with neurosurgical intervention in 30 cases of spontaneous intracranial hemorrhage, many of which simulated cerebral apoplexy; shortly thereafter 7 additional patients were included in the study.[4] This presentation is a follow-up report on the patients who survived the operation. Of the 30 patients 75% were between 40 and 66 years of age at the time of operation, the youngest 25, and the oldest 70 years of age; 15 were women and 15 were men. Blood dyscrasia was ruled out in all of these patients. Many of them were operated on before the routine use of arteriography had become established; this procedure was carried out in only four patients, and findings of aneurysm or vascular anomaly were negative in all instances. The preoperative clinical findings in all cases are listed in table 1.

TABLE 1.—*Summary of Preoperative Clinical Findings in Thirty Patients with Spontaneous Intracranial Hemorrhage*

	Patients		
Clinical Findings	No.	%	
History			
Hypertension	18	60	
Severe Headache	22	73	
Nuchal Rigidity (117 patients examined)	10	58	
Sensorium			
Awake	3	10	
Drowsy	13	43	90
Stupor or coma	14	47	
Dilated pupil on side of hemorrhage	7	23	
Choked disk	2	7	
Visual field defect	6	20	
Motor aphasia	4	13	
Mixed aphasia	3	10	
Hemiparesis	7	23	80
Hemiplegia	17	57	
Decerebrate rigidity	5	17	
Negative result of Wassermann test (25 patients examined)	25	100	
Spinal fluid (26 patients examined)			
Pressure elevated	24	92	
Red blood cells	20	77	
Roentgenographic evidence of pineal gland shift (22 patients, pineal gland calcified, 11)	11	100	

Indications for Operation

Although there are patients with spontaneous intracerebral hemorrhage who recover without operation and with varying degrees of disability, progressive hemmorhage results in death. It would be helpful to know what percentage of patients with proved intracerebral hemorrhage recover with medical treatment. However, without operation or autopsy, verification is impossible. Perhaps one could obtain such a series by cerebral angiography which might show displacement of vessels and thus provide indirect evidence of a clot; however, a tumor might show a similar picture. I do not know of any report of an adequate series in which, after cerebral angiography had suggested the presence of a hematoma, a patient recovered without undergoing an operation. The alternative is to review statistics of patients with intracerebral hemorrhage who were not operated on and to verify the hemorrhage by autopsy. Aring and Merritt[5] did this in 116 cases. They found that 8% of the patients had died within 24 hours, 21% within 1 to 4 days, 38% within 5 to 14 days, and 11% in 14 to 60 days. Rose[6] reported autopsy studies of 205 patients with intracranial hemorrhage, 80% of whom had died within 24 hours. Zimmerman[7] analyzed the records and autopsy material in 107 cases of spontaneous intracerebral hemorrhage. Ninety-four per cent of these patients had died after the first attack, and all of them were dead within five weeks of onset.

Cushing[8] in 1903 recognized the hopelessness of conservative treatment and stated, "In spite of the unfavorable results following operations in both my cases, the temporary amelioration of the severe symptoms is a sufficient justification for future attempts to afford surgical relief in certain carefully selected cases." Since Cushing's report, there have been many others, dealing with the removal of these hematomas, with varied mortality and morbidity.[9]

The indications for surgery in the patients reported in this paper were as follows: (1) symptoms and signs of increasing intracranial pressure such as drowsiness progressing to stupor or coma, stertorous respirations, decrease of the pulse rate to below 60 per minute and the respiratory rate below 16 per minute, increase in the spinal fluid pressure to above 160 mm. of water, and choked disks (if symptoms persisted for days); (2) neurological signs of focal brain involvement such as motor or sensory aphasia, visual field defect, hemiparesis, hemiplegia, or hemianesthesia, unilateral dilated pupil, unilateral convulsions, and decerebrate rigidity; (3) a roentgenogram of the skull showing a shift of the calcified pineal gland away from the suspected side of intracranial hemorrhage; and (4) an arteriogram showing a shift of arteries or veins which suggested a space-taking clot or showed an aneurysm or an arteriovenous malformation.

I avoided operating on patients with signs of extensive hemorrhage into the dominant internal capsule, because, if the patient survived, the added burden of motor aphasia in conjunction with the hemiplegia seemed intolerable. No patients with advanced cardiac, renal, or pulmonary disease were operated on. Decerebrate rigidity, although usually a sign for unfavorable prognosis, was no contraindication to operation, provided the patient's vital signs were favorable. A gratifying result (reported below) occurred in one patient with this complication.

The operation usually was an exploratory trephination which was enlarged to a small craniectomy. Occasionally a bone flap was elevated.

Mere aspiration of the liquid blood proved to be inadequate, and in the remaining patients it was necessary to remove the blood, aspirate or lift out the clot, and inspect and perform biopsy on the cavity wall. Frequently, only venous or capillary bleeding was found, which could be controlled by means of cauterization or the use of Gelfoam. I never could determine whether the venous bleeding was the cause of the clot or whether it resulted from the separation of brain tissue by the clot.

Biopsy of the hematoma and of the cavity wall was performed in 29 patients. An aneurysm was found in one and rupture of an artery without aneurysm in three; two patients were found to have a brain tumor, one a chorioepithelioma and the other a malignant melanoma; no obvious cause for the bleeding was found in the remaining 24 patients. If the cortex around the incision became concave at the end of the operation, the patient would usually survive; however, if the bleeding was controlled but the brain was markedly edematous, survival was unlikely.

Eleven of the 30 patients died in the hospital. Hence, the operative mortality for the entire series was 37%; or, if the two patients with hemorrhage into a brain tumor are excluded, 30%. Nineteen patients were discharged from the hospital after operation, and, in the 1952 report, the shortest follow-up period was three months and the longest seven years.

The anatomic location of the clot was an important factor in the death or survival of a patient and his subsequent neurological deficit. Twenty patients had hemorrhage into the internal capsule, seven into the temporal lobe area, and three into the subdural space.

Hemorrhage into Internal Capsule

Twenty patients suffered hemorrhage into the internal capsule, including the two with bleeding into a malignant tumor. Ten of these patients died in the hospital, the operative mortality thus being 50%, or 40% if the two tumor cases are excluded. Of the 10 patients who were discharged, 6 subsequently died, one after three months, 2 after five months, 2 after four years, and one after six years respectively.

Four patients are still alive at the time of writing (8, 9, 10, and 10 years, respectively, after operation). This constitutes a survival rate of 20% for eight years and longer for patients with hemorrhage into the internal capsule. The history of one of these patients is worth reviewing, because it illustrates a favorable outcome, over a long period, in what had appeared to be a hopeless situation.

Report of a Case.—A woman aged 25 years was admitted in January, 1949, with a history of right-sided headache for two days, followed suddenly by a left-sided hemiplegia and coma. She also had a history of hypertension. The patient was in a state of decerebrate rigidity, with stertorous respirations and a blood pressure of 230/120 mm. Hg. The spinal fluid was bloody, with a pressure of 260 mm. of water. Her condition was too critical for performance of skull roentgenography or angiography. Emergency performance of a small craniotomy revealed a large clot involving the right side of the internal capsule. After removal of the clot, the middle cerebral artery was seen spurting into the cavity; it was occluded with a silver clip. No aneurysm was found. This patient, under observation for 10 years, shows the maximal amount of recovery after severe internal capsule hemorrhage, her only handicaps being a useless hand, and unilateral partial drop foot. She has no headaches and leads an active life, doing her own light housework and working in her husband's drugstore. She had one convulsion nine years after operation and has had none since. On therapy with rauwolfia (Raudixin), her blood pressure fluctuates between 160 to 180 mm. Hg systolic and 90 to 100 mm. Hg diastolic.

Hemorrhage into Temporal Lobe and Its Adjacent Area

Seventy per cent of the seven patients with hemorrhage into the temporal lobe and its adjacent area were under 50 years of age; only 33% of the patients with hemorrhage into the internal capsule were below this age. Only two patients with hemorrhage into the temporal lobe area had hypertension, whereas 16 of the 20 patients with hemorrhage into the internal capsule had such a history. All of the patients with hemorrhage into the temporal lobe area survived the operation and were discharged from the hospital, but three of them subsequently died, and one could not be followed up.

Three patients who were operated on for hemorrhage into the temporal lobe area are still alive 7, 10, and 11 years respectively, after operation. This constitutes a survival rate of 50% for seven years and longer, as compared with a survival rate of 20% for eight years and longer for those patients who had been operated on for hemorrhage into the internal capsule. All three of the surviving patients have an occasional convulsion and are maintained on anticonvulsant therapy.

Hemorrhage into Subdural Space

Three patients had a spontaneous hemorrhage into the subdural space; one died 20 days after operation from an epidural hemorrhage, and the other two are alive 11 years after operation.

Neurological Deficits

All of the 10 patients who survived operation for hemorrhage into the internal capsule were left with serious neurological deficits. Five patients were completely hemiplegic and bedridden and subsequently died in nursing homes or hospitals, one three months, two five months, and two four years after operation. One hemiparetic patient was ambulant until six years after operation, when his condition deteriorated, and he finally died in a mental institution. One housewife is alert but hemiplegic eight years after operation but needs help in walking. One patient is alert but partially aphasic and hemiparetic nine years postoperatively and works in his wife's shop. Another is partially hemiplegic 10 years postoperatively and walks with a foot brace and cane. One housewife is alert and active 10 years after operation. She has drop foot and paralysis of the hand but walks with a foot brace and cane. Her case is given in detail elsewhere in this report.

All seven patients with hemorrhage into the temporal lobe area survived operation. Their neurological deficits are less disabling than those which occurred in the patients who had had hemorrhage into the internal capsule. The only deficit in three of these seven patients was a cut in the visual field, and all three continued with their preoperative occupations; one of them died 14 years after operation from heart disease, and another eight years after operation from hemorrhage into the opposite cerebrum. The third patient does housework 11 years after operation. Two of the patients with hemorrhage into the temporal lobe area have both a cut in the visual field and hemiparesis; both walk with foot brace and cane 10 and 7 years, respectively, after operation. One patient with astereognosis and hemiparesis died of a coronary attack seven months postoperatively. The remaining patient in this group of seven, who had mixed aphasia and hemiparesis, was discharged in an improved state but could not be located for follow-up investigation.

Postoperative Convulsions

Six (32%) of the 19 patients who survived operation have had one or more convulsion. Of the four patients who are still alive (two of them 8 and two 10 years respectively) after operation for hemorrhage in the internal capsule, one had a convulsion four months postoperatively and has had an occasional one since; another had a single convulsion nine years after operation and has had none since; the remaining two patients have had no attacks.

All three patients who are still alive 7, 10, and 11 years, respectively, after operation for hemorrhage into the temporal lobe area have had an occasional convulsion. The attacks began six years after operation in one case, after eight years in another, and after three years in the third. The attacks in all three patients have been controlled with anticonvulsants. The late onset of convulsions in some patients, six to nine years after operation, suggests that vascular changes about the healed lesion may be a factor. Howell[3d] reported an incidence of 35% of late "epilepsy" in 26 patients who survived operation for spontaneous intracerebral hemorrhage.

Autopsy Findings

Autopsies were performed on 10 of the 20 patients who had died either postoperatively or during the follow-up period. Hematomas into metastatic malignant brain tumors (chorioepithelioma and malignant melanoma) were found in two instances. Persistent hemorrhage, with softening and edema in an area of previous hemorrhage, was the most common cause of death. Atherosclerosis of the cerebral vessels was a frequent finding.

Focal hemorrhages into the pons in addition to the hemorrhage into the cerebral hemisphere occurred in three patients. These hemorrhages were probably caused by obstruction of venous drainage from the brain stem by the edematous cerebral hemispheres. However, Kaplan[10] believes that the hemorrhage into the pons is arterial and that this complication is found frequently in patients with spontaneous hemorrhage into the cerebral hemisphere. One patient who survived removal of a large hematoma from the left temporal lobe died nine years later from a massive hemorrhage into the opposite hemispheres and pons; no aneurysm was found.

Comparison of Long-term Follow-up Data with Other Follow-up Studies

I could find no reports of a series comparable to mine that had been analyzed with reference to location of the hemorrhage into the internal capsule versus other cerebral areas. Moreover, few of these studies dealt with long-term follow-up investigation. I had previously presented an analysis[4] of operative cases of spontaneous intracerebral hemorrhage which I had found in the literature through 1950. One hundred five cases had been reported by 20 different authors. Most of them had reported only a few cases; for example, 17 of the 19 reports had been on groups of less than 10 patients. The operative mortality varied from 0 to 100%.

The following surgeons reported 10 cases or more and some of their data might be comparable: Hamby[9a] described 14 cases with a mortality of 14%. However, none of his patients were designated as having hemorrhage into the internal capsule, and three had a hemorrhage into a metastatic tumor. Gurdjian and Webster[3b] published case reports of 11 patients with large hemorrhagic collections. Three of these patients had hypertension. One clot may have involved the internal capsule, and the rest were in the temporoparietal or temporo-occipital lobes. The operative mortality was 18%. Cerebral angiography was performed in 10 patients, and angiomas were found in 2; no berry aneurysms were reported. There were no follow-up reports on the survivors. Odom and co-workers[11] reported 106 cases of intracerebral hematoma. Fifty-five had been due to hypertension, 28 to congenital aneurysms, 9 to angiomatous malformations, and 14 had been of unknown etiology. Of 25 of their patients who had been operated on 5 died, an operative mortality of 20%. The authors gave no case reports or follow-up data. Their report dealt primarily with the pathology of these lesions. Ferey[12] reported 32 operative cases of intracerebral hemorrhage, 29 in the cerebrum and 3 in the cerebellum, with an operative mortality of 25%. However, he provided no case reports or follow-up studies. Beck[9b] reported 11 operative cases of spontaneous intracranial hemorrhage in patients between 35 and 62 years of age. Eight had had a history of hypertension. Six hematomas were located in the temporal, parietal, or occipital lobes; three in the frontal lobe; one in the middle of the fissure of Rolando; and the other in the inferior frontal lobe. Angiography was performed in 10 of 11 patients, but no vascular anomalies were reported. Six of the hematomas were subcortical and five were deep in the brain. All of Beck's patients survived operation and their progress was followed for from four months to three and one-half years. Beck stated that the results were excellent in one patient, good in eight, fairly good in one, and fair in one. No deaths occurred in the entire series. Since Beck did not give any case reports, it is difficult to determine how many of the lesions were in the internal capsule.

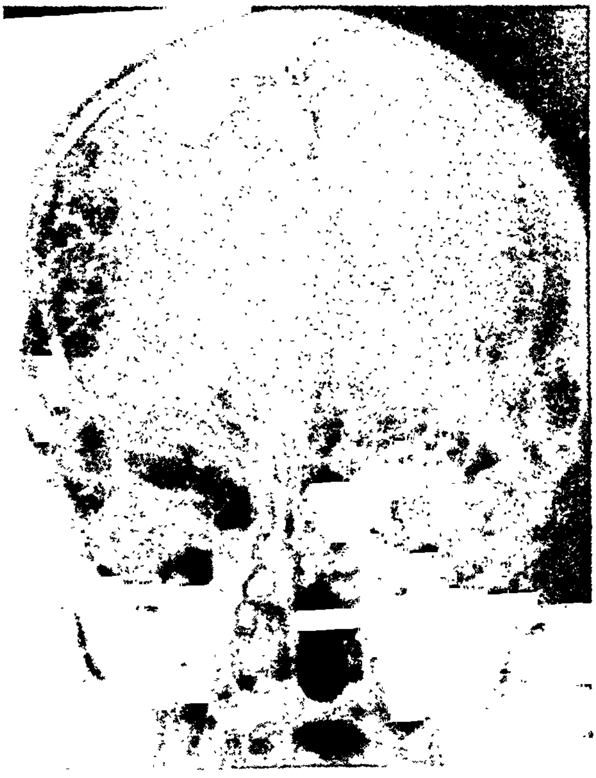

Fig. 1.—Angiogram showing arteriovenous malformation.

The report by Howell[3a] in 1957 of operative results in 33 patients with massive cerebral hemorrhage appears comparable to the group I am reporting. Howell reported a surgical mortality of 21% for his entire group, 43% for the group of patients with hypertension, and 5% in the nonhypertensive group. Cerebral angiography was performed in 24 of his patients. He found arterial hypertension to be the only demonstrable cause of hemorrhage in 13 patients; 5 patients (one of whom had hypertension) had a proved ruptured berry aneurysm; in 9 patients an arteriovenous malformation was shown by angiography; and in the remaining 6 patients no cause for the hemorrhage was found. He believed hypertension to be the most important factor influencing the outcome of treatment. Epilepsy developed as a delayed complication in 35% of the survivors in Howell's group.

Fig. 2.—Patient four weeks postoperatively after removal of malformation and intracerebral hematoma in right parietal lobe.

Summary of Additional Patients Operated on but not Included in Long-term Follow-up Investigation

Since my report in 1952,[4] eight additional patients have been operated on, one each by my associates, Drs. Wycis, Murtagh, and Lin, and the rest by Dr. Aldana and myself. Seven of this group of patients had hematomas involving the internal capsule and one had hemorrhage into the parietal lobe. Six patients had marked hypertension. One patient died the first day after operation from massive hemorrhage into the cerebrum and into the pons. Another died three weeks postoperatively from recurrent hemorrhage into the cerebrum. No autopsy was performed in either case. Six patients survived the operation and were discharged from the hospital. Thus, the operative mortality in this small group of eight patients was 25%.

TABLE 2.—*Differential Diagnosis of Common Causes of a "Stroke"*

	Hemorrhage		"Thrombosis"	Embolism	Brain Tumor
	Intracerebral	Subarachnoid			
Age group	Middle and old	Young and middle	Middle and old	Young and middle	All
Onset	Sudden	Sudden	Gradual	Sudden	Gradual
Progression	Usually rapid	Usually rapid	Usually gradual	Maximum deficit early	Usually gradual
Headache	Severe and usually on side of hemorrhage, early	Severe and generalized	Mild or absent; severe only if edema present	Mild or absent; severe only if edema present	Severe, early
Nuchal rigidity	Absent until bleeding ruptures into subarachnoid space	Marked and early	None	None	None, unless herniation of brain
Sensorium	Drowsy to coma	Drowsy to coma	Usually clear early, impaired if edema present	Usually clear early, impaired if edema present	Varies, clear early
Blood pressure	Hypertension (50%)	Usually normal early	Normal or moderately elevated	Normal or moderately elevated	Normal, but increases as intracranial pressure increases
Eye grounds					
Retina	May show hemorrhage	May show hemorrhage	No hemorrhage	No hemorrhage	May show hemorrhage if severely choked disk
Blood vessels	Hypertensive changes	Normal	Arteriosclerotic changes	Normal, or emboli visible	Veins dilated and tortuous
Disk	Normal, choked later	Normal or choked	Normal	Normal	Choked (40%)
Spinal fluid					
Pressure	Increased	Increased	Normal (130-160 mm. H_2O)	Normal	Increased
Color	Bloody in over 50%	Pink to frank blood, usually cherry red	Clear	Clear	Clear
Pineal gland on skull roentgenograms	Shifted to one side by clot	No shift	No shift unless edema present	No shift unless edema present	Shifted
Cerebral angiogram	Shift of vessels; visualization of aneurysm or arteriovenous malformation	Aneurysm or arteriovenous malformation	Occlusion of artery in cerebrum or internal carotid artery in neck	Occluded vessel may be visualized	Shift of vessels; tumor visualized by concentration of radiopaque medium

One woman, now aged 53 years, is still alive seven years after operation. She walks with a brace and cane; her blood pressure varies between 130 to 150 mm. Hg systolic and 80 to 90 mm. Hg diastolic. She had two jacksonian convulsions three years after operation but has had none since. She is on therapy with phenobarbital and reserpine (Serpasil). One male patient, now aged 59 years, is hemiparetic but walks with a leg brace four years after operation. He is alert and can read but he cannot practice his profession as a minister. His blood pressure was normal both before and after operation. Another male patient, now 22 years of age, had an arteriovenous malformation (fig. 1) and an intracerebral hematoma in the right parietal lobe. He has made a good recovery, retaining only a slight weakness of his foot (fig. 2) and he is working as a painter two and one-half years after operation; he also had two jacksonian convulsions.

The remaining three patients, all with marked hypertension and with hemorrhages into the internal capsule, have had their postoperative progress followed for one to two years. All are bedridden, with marked neurological deficits, and are in institutions for the chronically ill.

Cerebral angiography was performed in five of the eight patients; no berry aneurysm was seen in any one of the five, but an arteriovenous malformation was seen in one patient; a shift of the arteries and the deep cerebral veins, which suggested a space-taking clot, occurred in two patients; and no abnormality was found in the remaining two patients.

Importance of Differential Diagnosis of Cerebral Hemorrhage from Embolic or Occlusive Vascular Disease (Thrombosis) and Disease of Cerebral or Carotid Arteries in the Neck

In view of the recent tendency to popularize the use of anticoagulants in "stroke cases," it is important to emphasize the danger of the use of such substances in a case of cerebral hemorrhage which has been diagnosed as "cerebral thrombosis" or embolism. (The term cerebral thrombosis should be used only if confirmed by pathological examination.) Table 2 may be of help in the differential diagnosis of these conditions. However, cerebral softening may occur in the field of irrigation of an artery which has been occluded by "thrombosis" or embolism. Blood vessels in the softened area may weaken and rupture. Experimental studies with use of anticoagulants in animals with cerebrovascular occlusive disease show that these substances increase the bleeding into infarcts.[13] The danger in the use of anticoagulants in such a situation is obvious. The use of these drugs in the treatment of embolic, occlusive, or "insufficiency" states of the cerebral blood vessels should be abandoned until further experimental studies definitely prove the value of such therapy.

Summary

The operative mortality for removal of hematomas from the temporal lobe area is surprisingly low, and in the series here reported no postoperative deaths occurred. The residual neurological deficit is compatible with a useful and productive life. Fifty per cent of these patients are still alive 7 to 11 years after operation.

The operative mortality for removal of hematomas from the internal capsule is high, and both the preoperative and postoperative neurological deficit is marked. Probably all of these patients would have died without operation. Some of those who survived are active within the limitations imposed on them and are glad to be alive. Twenty per cent of this group are still alive 8 to 10 years after operation. This long-term survival rate compares favorably with that of patients operated on for malignancy of the lung, stomach, and other areas.

Prompt neurosurgical intervention for spontaneous intracerebral hemorrhage which causes focal neurological signs and progression in intracranial pressure will save lives.

FREEDOM IN THE PRESENCE OF AN AUTHORITY FIGURE.—The analyst, although he stands as the advocate of individual integrity, inviolability, and spontaneity, is at the same time the initiator and agent of a process that for painfully long periods of time must be traced through a maze of submissiveness and intrusiveness. The necessity to assist the patient to the point of his "ego's freedom to choose" along a route of dependence, via the psychoanalytic processes of dynamic and genetic regression, constitutes a paradox, upon the solution of which depends the outcome of the therapy. There is no lessening of its stress from the fact that this paradox confronts every parent and indeed every authority-figure in a society where the privileges and obligations of the individual are traditionally honored.—S. L. Olinick, M.D., The Analytic Paradox, *Psychiatry*, November, 1959.

RECENT DEVELOPMENTS IN FORENSIC PATHOLOGY

Russell S. Fisher, M.D., Baltimore

Forensic pathology has become a subspecialty in the field of pathology within the past five years. The increasing contribution of pathology to the elucidation of the problems of trauma and the solution of the legal aspects of these problems emphasizes the great need for broadening the horizon of pathologists. The vast scope of this field is recognized when one considers that practically all homicide cases, nearly all compensation cases, and about 4 of every 10 tort cases or damage actions heard in the courts today involve medical testimony and require expert medical survey of the evidence on which the final decisions will be based.

The use of scientific developments in pathology in the solution of medicolegal problems, especially in the investigation of sudden and violent death, in the public interest has been far slower than any other application of pathology in the last 100 years. Indeed, except in a few cities and in the state of Massachusetts, it can be said that no progress occurred until 1939, when Maryland abolished its coroner system and established a centrally directed statewide medicolegal department. This included the adequate legal requirement that trained forensic pathologists assist local physician deputy medical examiners, whenever an autopsy was indicated, and a central toxicological facility. Virginia adopted this system in 1946, and a few other states have initiated improved coroner systems in the last decade. Even with this progress it was not until the last three years that forensic pathology gained recognition as a bona fide subspecialty in the field.

New Status of Forensic Pathology

The sequence of important events in the development of forensic pathology as a subspecialty of pathology is as follows.

1. The activities of the Committee on Medicolegal Problems of the American Medical Association under the leadership of such outstanding men as Regan, Holloway, and Moritz.
2. The establishment of the Committee on Forensic Pathology of the College of American Pathologists in 1954. This committee has been especially active in persuading the American Board of Pathology to establish the subspecialty certification in forensic pathology, which will be described subsequently in this paper.
3. The establishment by the American Society of Clinical Pathologists of its Council on Forensic Pathology, which is dedicated to the continuing education of pathologists and the improvement of the caliber of practice in this field.
4. The establishment in 1958 of the Registry of Forensic Pathology at the Armed Forces Institute of Pathology under the sponsorship of the College of American Pathologists. The function of this registry is to collect, classify, study, and register cases of a medicolegal nature. As a repository for such cases, the registry makes available material for research and teaching. It is anticipated that sufficient material can be assembled from contributing sources to provide a pool of pathological material to permit (*a*) research on unsolved problems of forensic pathology; (*b*) preparation of lantern slides, photographs, and microslides to be used in classes, seminars, and workshops; (*c*) use of gross material for seminars, schools, board examinations, museum specimens, and research; and (*d*) accumulation of data for publication.
5. The initiation of subspecialty certifications in forensic pathology by the American Board of Pathology. The first certificates were awarded at the meeting of the Board in Boston in April, 1959. The first examinations in this subject will be given in November, 1959, in New Orleans. The Board, in conjunction with the American Medical Association's Council on Medical Education and Hospitals, will inspect and approve centers for training in forensic pathology, thus establishing criteria of adequacy for practice and for training facilities for young men aspiring to work in this field.
6. During the past 12 years the National Municipal League has campaigned actively for better medicolegal statutes. Their booklet entitled "A Model Medicolegal Investigative Law" has been widely distributed and is of great value to local groups seeking to improve or replace their antiquated coroner systems.
7. The continuing carnage of automobile accidents and the realization, impressed on the public by the National Safety Committee and its Alcohol Test Committee, of the role of alcohol in many of these deaths has been instrumental in getting chemical test legislation passed in 28 states. Pa-

From the Office of the Chief Medical Examiner of Maryland and Division of Forensic Pathology, Department of Pathology, University of Maryland Medical School.

Read before the Section on Pathology and Physiology at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 11, 1959.

thologists have been in the forefront in many of the organized drives necessary to obtain such legislation, and they continue in supervision of the laboratory work integral to the implementation of these statutes.

These important items of progress may be said to have established forensic pathology on a firm basis as a subspecialty of pathology, dedicated to the application of scientific developments to the solution of problems in the public interest. The intensive and continuing support of the entire community of physicians in the United States is highly desirable in an effort to assure the courts and the public that medicine is indeed interested in the solution, on a scientific basis, of the many problems of medicolegal nature. The vast scope of this field is readily recognized when one considers that practically all homicide cases, nearly all compensation cases, and about 4 of every 10 tort cases or damage actions heard in the courts today involve medical testimony and require expert medical survey of important parts of the evidence on which the final decisions will be based.

Research in Forensic Pathology

With the maturation of forensic pathology as a respected member of the scientific disciplines there has been a tremendous emphasis in research on the pathology of trauma and its toxicological implications.

Perhaps the most widely studied of the new chemicals are the organic phosphates. These extremely toxic agents cause a marked depression of a vital enzyme system in poisoned persons. Demonstrations of such enzyme depression by application of chemical and histochemical techniques in blood and tissue specimens removed at autopsy are examples that may be of great use to forensic pathologists. The organic phosphates have been used as suicidal and homicidal agents.[1] More important has been the dissemination of information concerning the diagnosis of organic phosphate toxicity and the necessity of administering massive doses of atropine for its treatment.

Thallium poisoning has been recognized as an important medicolegal problem. The published experiences of Matthys and Thomas,[2] that fatal thallium poisoning is frequently confused with death due to encephalitis or the Guillain-Barré syndrome, has alerted pathologists without particular interest in the forensic field to the confusing picture caused by this chemical.

Many studies in the field of alcohol adaptation and tolerance have appeared in the last few years as well as important contributions describing the acidosis and hypoglycemia occasioned by the ingestion of compounds containing mixtures of ethyl and methyl alcohol, bay rum, isopropyl rubbing compound, and various other alcoholic substances, commonly described as "smoke."

Barbiturate addiction has been described as a clinical syndrome within the past few years, and the monumental work of Maurer and Vogel[3] has placed the diagnosis of this recently recognized addiction on firm clinical ground.

Such unusual poisonous agents as jellyfish and those unusual piscines known as "weevers," which are capable of producing extremely painful and even fatal wounds to swimmers and divers along the Eastern Atlantic and Mediterranean Coasts, recently have been described. Fatal poisoning as a result of eating the liver and flesh of the "blowfish" (tetraodon) gathered along the coast of Florida is the subject of a recent report of forensic interest.[4]

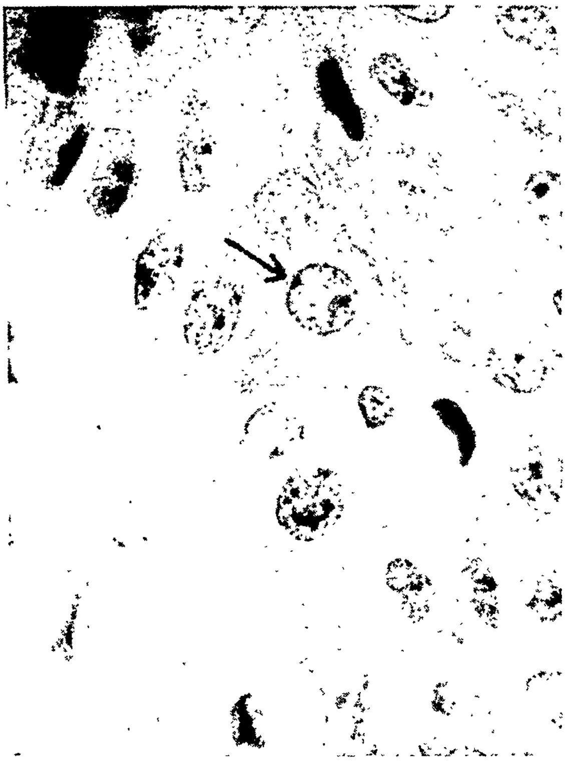

Fig. 1.—Female sex chromosome body in epithelial prickle cell (*arrow*) (× 900).

Finally, in the area of chemical poisoning there is renewed interest in carbon monoxide poisoning. A careful study by English colleagues, which demonstrates that some 30% of persons over 65 years of age cannot smell coal gas in concentrations of less than 50 parts per million (a potentially lethal level), has emphasized the ineffectiveness of odor alone as a danger signal for the accidental escape of unburnt gas.

Identification from immature bones and from the teeth as well as determination of sex by studies in cell morphology, particularly sexing by study of the chromatin particles in the nucleus of leukocytes and in fetal tissue (fig. 1), may be accepted as evidence of the increasing contributions to the literature of forensic pathology by the anatomist, the dentist, and the anthropologist.

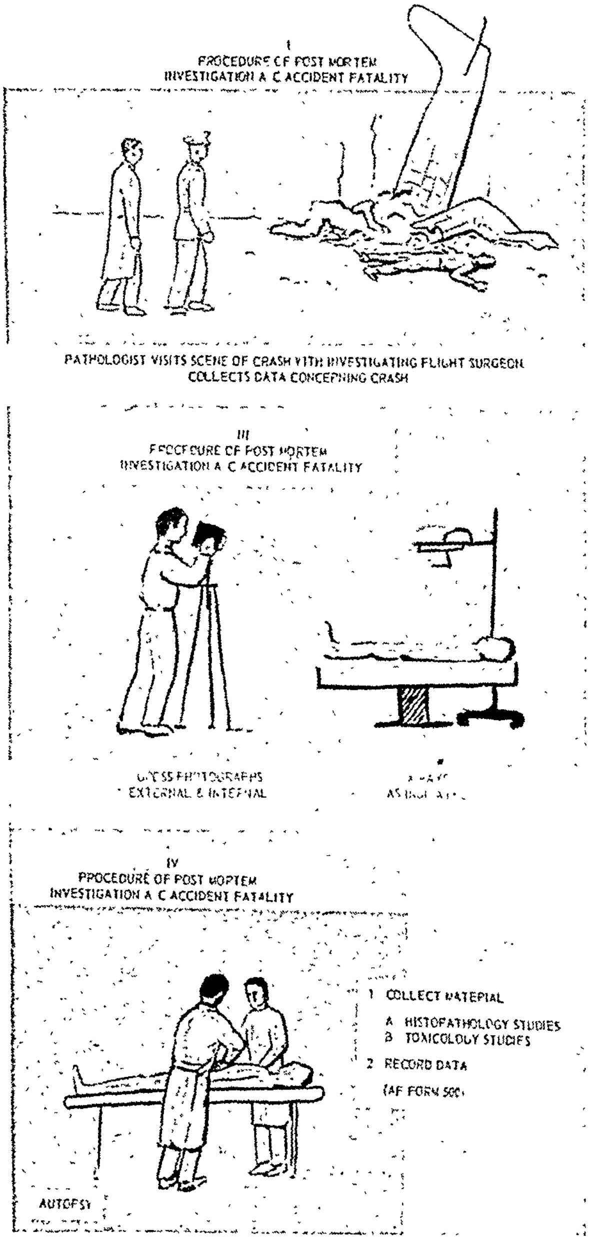

Fig. 2.—Selected procedures in investigation of aircraft accidents (illustrations provided by courtesy of aviation pathology section, Armed Forces Institute of Pathology).

A tremendous impetus in the study of the pathology of injury has been generated by use of the new supersonic airplanes in the U. S. Armed Forces and of the high-speed jet aircraft now appearing in commercial air-transport operations. One of the most interesting presentations in this area is that of Lawton[5] who demonstrated in pressure chamber studies that "pilots" were occasionally observed to collapse at pressures ordinarily considered to simulate safe altitudes. He observed that these patients were anxious and were hyperventilating. Fifty per cent of the trainees who encountered difficulties had usually had inadequate breakfasts, and in many cases hypoglycemia could be shown to be a factor in pilot failure. Such simple changes as alteration in the dietary regimen led to prevention of hyperventilation and hypoglycemia, with a consequent marked decrease in pilot-error accidents at one Air Force training base. The organization of a team of pathologists and toxicologists at the Armed Forces Institute of Pathology and of similar groups in civilian medicolegal practice stresses the importance of the pathologist as a member of the investigating group studying aircraft accident fatalities (fig. 2). The potential contributions of pathologists in the area are legion, yet the earliest documented recognition of the pathologist as an important member of the team has appeared within the last five years.

The increasing complexity of surgery made possible by surgical research and improved anesthesia has served to focus attention on the problems of anesthetic causation or contribution to operative death. The recognition of the dangers of excess carbon dioxide accumulation in patients with chronic chest disease and of the causation of atrial fibrillation by electric shocks in industrial situations are two examples of recent progress. The increasing perception that the cause of anesthetic fatalities is more often concealed in the method rather than in the type of anesthesia administered has been emphasized by Ruth and co-workers,[6] who have made an outstanding contribution to the field. These authors list hypoxia, hypercapnia, excessive anxiety, and errors in dosage as the most important factors in cardiac asystole. Other interesting studies in the field include those of Hale and Moraca,[7] who showed tracings obtained when the heart is under the direct control of the operator who causes cardiac asystole by injection of potassium citrate into the coronary tree. Surely, from studies such as these will arise a better understanding of the surgically and anesthetically produced cardiac arrests which are such a bane in the operating room today.

No review of recent developments in forensic pathology would be complete without some mention of "whiplash" injuries and the many attempts on the part of orthopedic surgeons, pathologists, and even attorneys to describe and delimit adequately the pathogenesis and the sequelae of injuries sustained by sudden disproportionate acceleration or deceleration of movements of the head and trunk.

Contributions of Forensic Pathology

The contributions in the medicolegal field of medicolegal pathologists to the recognition of anaphylactic reactions to penicillin deserve mention. Penicillin and other new therapeutic agents require continuing study in the determination of their dangers as well as their advantages.

The blood-grouping tests that have been developed in the past 15 years for use in disputed paternity proceedings are now recognized as compelling evidence in almost all states in the union. Just when we have begun to feel that the scientific method of disproving paternity was approaching the ultimate, the report of Sussman and Schatkin[8] emphasized the frailty of human nature. They reported 67 cases of disputed paternity proceedings in which the man did not contest the allegation of paternity. After the litigation was finished, A-B-O and M-N tests were run on a voluntary basis. In 12 of the 67 cases the serologic tests proved that the person who had submitted to the charge of paternity was not, in fact, the father of the infant in question.

Among the most disconcerting experiences in the life of a pathologist is that of reaching the conclusion of the gross, microscopic, and chemical studies in a case of sudden death and realizing that he has not been able to demonstrate, with the tools available, the cause of death. A small portion of such cases will now be solved by the development and refinement of the precipitin test for hypersensitivity. This test depends on the fact that in the test tube, particularly in agar-stabilized preparations, a positive result of a precipitin test may be demonstrated with use of a potent antigen and the serum or macerated tissue extract of the victim. Thus, in a recent case of hypersensitivity to horse serum in which the issue in dispute was whether the sudden death was due to sensitivity to penicillin or to the horse serum vehicle for tetanus antitoxin given simultaneously, our laboratory was able to demonstrate an excellent precipitin reaction in the tubes containing the patient's serum and the horse serum but no reaction in tubes containing the patient's serum and penicillin. Much further work is needed in refining this technique, but it has been demonstrated to be successful and leads one to hope that, in the near future, immunological studies will lead to the solution of a considerable number of medicolegal cases by demonstration of sensitivity reaction in cases of anaphylactic death.

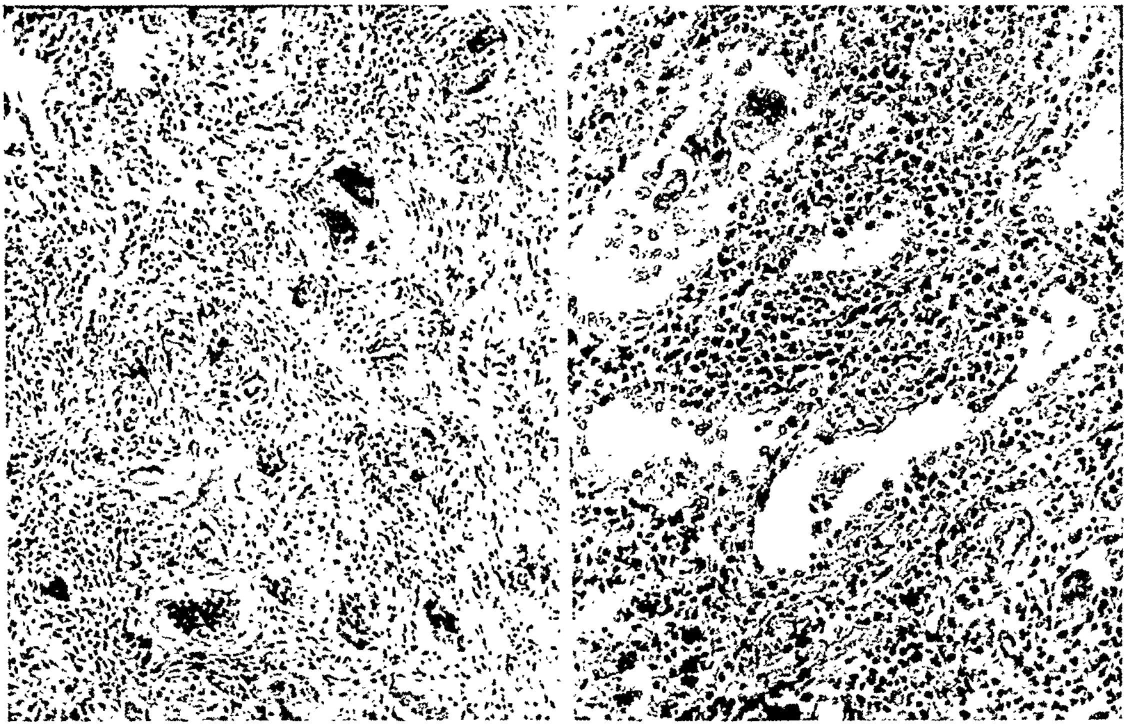

Fig. 3.—Pulmonary lesions in patients with, *left*, berylliosis (× 70) and, *right*, Hamman-Rich disease (× 100), selected to show similar granulomatous reaction.

The Gettler test for drowning was described nearly two decades ago. It depends on the assumption that, in persons drowning in sea water, the ingestion of highly saline water will lead to an increased blood chloride concentration in the left heart as compared to the right and, in persons drowning in fresh water, a dilution of blood chloride in the left heart as compared with the right. The test was widely used but was subject to considerable variation and, of course, was useless when drowning occurred in "brackish" water. The development and application to human cases by

Durlacher and co-workers[9] of plasma-specific gravity-dilution procedures has offered great assistance to the medicolegal pathologist in his studies of putatively drowned victims. The principle is simple, depending as it does on the fact that ingestion of water, whether fresh or salt, of low specific gravity leads regularly to the dilution of the plasma in the left heart. With the use of corrections for the contribution to the specific gravity by hemoglobin released through hemolysis of the cells, the procedure gives a great deal more certainty to the diagnosis of drowning than has been possible heretofore; typical findings are shown in the table.

Typical Atrial Plasma Differences in Victims of Drownings and Controls

	Specific Gravity*		
Cause of Death	L.	R.	L.-R.
Fresh-water drowning	1.0307	1.0349	—0.0042
Brackish-water drowning	1.0306	1.0323	—0.0017
Salt-water drowning	1.0319	1.0468	—0.0149
Cardiac failure	1.0291	1.0267	+0.0024
Hanging	1.0367	1.0381	—0.0014
Electrocution	1.0318	1.0287	+0.0031

* L. = left atrium; R. = right atrium. Specific gravity is corrected for hemolysis.

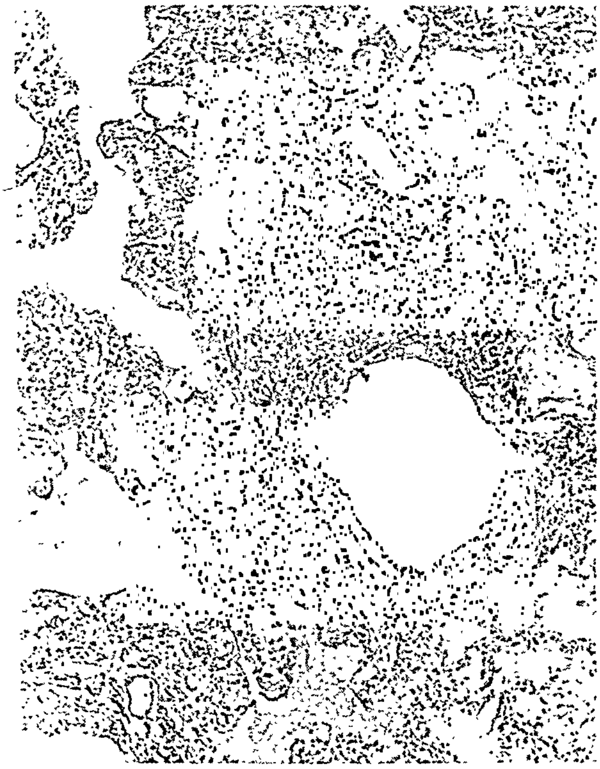

Fig. 4.—Lung of patient with acute "silo-filler's disease," showing endobronchiolitis and surrounding interstitial pneumonitis (× 70).

Pathological studies of the lungs in the last few years have produced three interesting conditions with which the medicolegal pathologist must be familiar. These are the diffuse interstitial fibrosis known originally as the Hamman-Rich syndrome which may readily be confused with beryllium pneumonitis. The second is the recently described granulomatous interstitial pneumonitis (fig. 3) resulting from the handling of a variety of dusty, moldy organic materials, described by Dickie and Rankin[10] under the title "farmer's lung." The third member of the pulmonary triumvirate of recent years is known as "silo-filler's disease"[11] (fig. 4 and 5). The occurrence of bronchiolitis obliterans due to inhalation of higher oxides of nitrogen, principally nitrogen dioxide, has been recognized as a laboratory accident in years past. Its recognition by Leib and co-workers[11] as the underlying pathological process leading to chronic pulmonary insufficiency in farmers who developed pneumonitis during silo filling is an excellent example of recognition of a chemical poisonous agent by its effect on the lung, with subsequent proof that the agent was, in fact, present in the environment where the disease occurred.

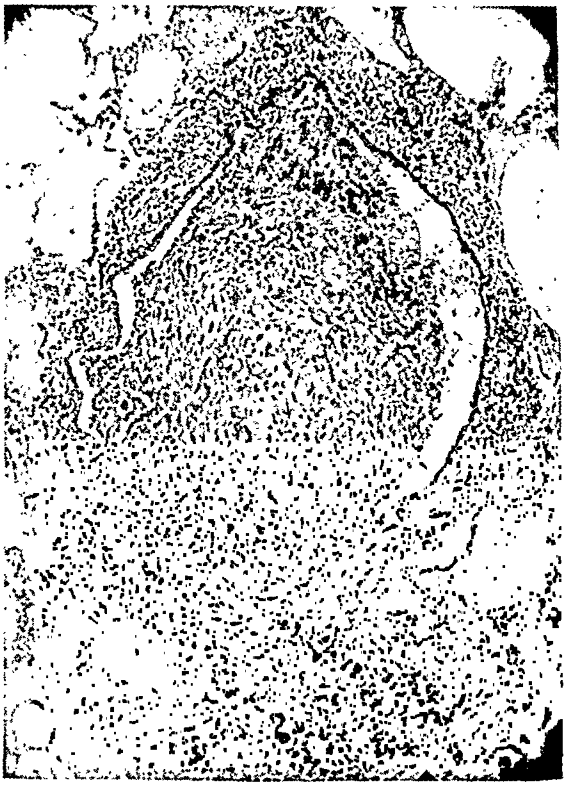

Fig. 5.—Obliterative endobronchiolitis; a later stage of "silo-filler's disease" or nitrogen dioxide poisoning.

Summary

Forensic pathology has emerged as a full-fledged subspecialty in the field of pathology within the past five years. The increasing importance of the contribution of pathology to the elucidation of the problems of trauma and the solution of the legal aspects of these problems emphasizes the great need for broadening the horizon of pathologists in the pathology of trauma.

Outstanding developments in the research laboratory in the past years include specific gravity procedure in downing tests, special techniques in investigating aircraft accidents, recognition of such new types of poisoning as "silo-fillers disease" and "farmer's lung," the development of a precipitin test to confirm hypersensitivity deaths, and studies in alcohol adaptation and tolerance.

BILATERAL MIDLINE FIXATION OF CRICOARYTENOID JOINTS AS A SERIOUS MEDICAL EMERGENCY

Ira A. Polisar, M.D., Benjamin Burbank, M.D., Leon M. Levitt, M.D., Hyman M. Katz, M.D.
and
Thomas G. Morrione, M.D., Brooklyn, N. Y.

Inspiratory stridor, nonresponsive asthma, intermittent respiratory difficulty with cyanosis, sudden collapse, shock, and coma can all be observed in patients with midline fixation of the right and left cricoarytenoid joints. Each of these articulations has a ligamentous capsule lined by a synovial membrane and normally permits gliding and rotatory movements of the apposed articular surfaces. When they are ankylosed by local or general arthritis the consequences are serious. The case histories of a man 47 years of age and two women 51 and 56 years of age illustrate the severity of the symptoms, the bad effects of administering sedatives, the importance of considering tracheostomy, and the possibility of a fatal complication. The two female patients were permanently relieved by arytenoidectomy.

Hidden almost exclusively in the specialized otolaryngologic literature under the seemingly benign title "cricoarytenoid arthritis" appears a bizarre syndrome to which we would like to direct the attention of clinicians. A patient may present any one or a combination of the following signs: inspiratory stridor, nonresponsive asthma, intermittent respiratory difficulty with cyanosis, sudden collapse, shock, or coma. Prompt recognition and adequate treatment are lifesaving. This entity may result from bilateral midline fixation of the cricoarytenoid joints.

Background

Anatomy.[1]—Each of the cricoarytenoid joints has a ligamentous capsule lined by a synovial membrane. The capsule of the joint is strengthened posteriorly by a band which is inserted into the base of the arytenoid cartilage. The movements

---

From the Division of Otolaryngology, Department of Surgery, and Department of Medicine, State University of New York, Downstate Medical Center; the departments of otolaryngology, medicine, and pathology, Long Island College Hospital; and the Brooklyn Veterans Administration Hospital.

which take place at the cricoarytenoid joint are gliding and rotatory. The structure of this joint places it in the category of diarthrodial articulations: it is composed of two cartilages which move freely on each other; there is a definite joint capsule between them; each has an articular surface; and each surface and the capsule are lined with a synovial membrane.

Fig. 1 (case 3).—Articular surface of arytenoid cartilage showing pannus-like thickening on surface of cartilage. Note disarrangement of cartilage cells. Superficial layers consist of dense fibrillar connective tissue. Hematoxylin-eosin stain (× 125).

Histopathology.—Histopathological material is exceedingly scarce since the cricoarytenoid joint is not accessible for biopsy. A biopsy specimen of the larynx proper does not yield any fruitful information, and such biopsy reports consist almost solely of statements to the effect that the larynx shows no malignancy or specific infection such as tuberculosis. Autopsy material is very limited, because the joint is not examined routinely. Histological sections of the excised arytenoid cartilages reveal destruction of the superficial cartilaginous cells. This change is accompanied by fraying and roughening of the surface. The cartilage shows irregular replacement by fibrous tissue. The pathological specimens show minimal fibrosis and lymphocytic infiltration of the small amounts of synovial tissue adherent to their edges. Figure 1 shows the right arytenoid cartilage from the patient in case 3 (see the table). Figures 2 and 3 show low-power and high-power magnifications of the arytenoid cartilage from the patient in case 5 (see table).

History.—Recent American and foreign literature contains few references to this condition. However, older otolaryngologic textbooks[2] and journals[3] described this condition under such titles as "Arthritis," "Ankylosis and Rheumatism of the Cricoarytenoid Joints," "Arthritis Deformans of the Larynx,"[3a] and "Perichondritis of the Larynx." More recently, several authors[4] have revived interest in this subject. In 1958, one of us (I. A. P.)[5] reviewed the entire subject in detail.

Clinical Manifestations

While Montgomery[6] has described an acute state of this condition in which there is dysphagia, hoarseness, tenderness over the larynx, and acute congestive edema of the arytenoid cartilages and the arytenopiglottic folds, none of our patients presented any of these findings. Actually, the striking feature of our patients was that their bizarre symptoms distracted attention from the larynx as the basic seat of the difficulty. Our own experience would seem to indicate that this disorder is an insidious, progressive, pathological process of a low-grade inflammatory or degenerative nature which does not produce early symptoms and signs of laryngeal involvement. So insidious and seemingly benign is this process that most of our patients had been diagnosed as psychoneurotics and were advised to have psychiatric evaluation.

We have been impressed by a history of stridor, "asthma," dyspnea, recurrent exacerbations and remissions, and, finally, by the dramatic and sudden collapse to which these patients may be subject.

Symptoms and Treatment of Eight Patients with Bilateral Midline Fixation of Cricoarytenoid Joints

Cases			Duration, Yr.	Symptoms*			Treatment	
				Asthma	Arthritis			
					On Physical Examination	History		
No.	Age, Yr.	Sex					Operation	Result
1	57	M	10	Yes	No	No	Arytenoidectomy	Excellent
2	58	M	8	No	No	No	Arytenoidectomy	Excellent
3	56	F	7	Yes	No	No	Arytenoidectomy, bilateral	Excellent
4	28	M	4	No	No	No	Arytenoidectomy	Excellent
5	51	F	5	Yes	Yes	Yes	Arytenoidectomy	Excellent
6	25	M	1	No	No	Yes	Arytenoidectomy	Excellent.
7	47	M	2	No	No	No	Tracheostomy	Died
8	70	M	1	No	Yes	Yes	Tracheostomy	Died

* All patients had stridor, minimal hoarseness, and dyspnea on exertion.

Stridor.—In every instance, questioning revealed that these patients are aware that they make loud noises which are most marked during inspiration. This crowing inspiratory stridor is easily confirmed by observation at the bedside. A carefully taken history reveals that the stridor is most marked when the patient is inactive, relaxed, or asleep and least marked when the patient is alert and active. We believe that patients are able to modify their extraordinary laryngeal obstruction when they are alert and that loss of this compensatory mechanism accounts for the stridor when they are relaxed or asleep. The validity of this thesis has been proved in several of our patients when they were given sedatives and when we observed how quickly the inspiratory stridor became accentuated. This reaction, in some instances, was promptly followed by severe cyanosis to such a degree that the need for emergency tracheostomy had to be considered.

"Asthma."—Most of our patients gave a history of being treated for asthma. In every instance in which this diagnosis was entertained, conventional methods of therapy were unsuccessful. In a review of the findings in these cases there was no familial or personal history of allergic manifestations; peripheral blood and respiratory secretions did not reveal eosinophilia; and most important, both patients and physicians were well aware that this disorder was an inspiratory rather than an expiratory difficulty.

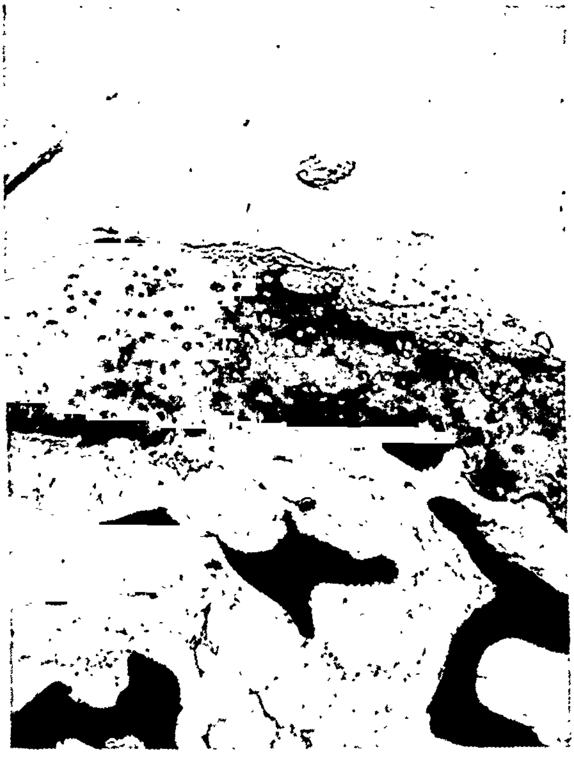

Fig. 2 (case 5).—Arytenoid cartilage showing destruction and roughening of cartilaginous articular surface. Hematoxylin-eosin stain (× 40).

Dyspnea.—Dyspnea has not been a serious complaint of most of these patients. With the passage of time, or in the presence of a superimposed upper respiratory infection, they have noted slight to moderate exertional dyspnea, but this symptom rarely has been disabling.

Exacerbations and Remissions.—Exacerbations usually were accompanied by an upper respiratory infection and were apt to continue for a long time after the manifestation of the concomitant infection had disappeared. There have been instances, however, in which exacerbations occurred without the stimulus of a superimposed respiratory infection or of any other etiological agent which we have been able to discover. In this latter respect, it seems to follow the course of rheumatoid arthritis involving the more commonly affected joints. Remissions have occurred in a similarly unexplained and unpredictable fashion.

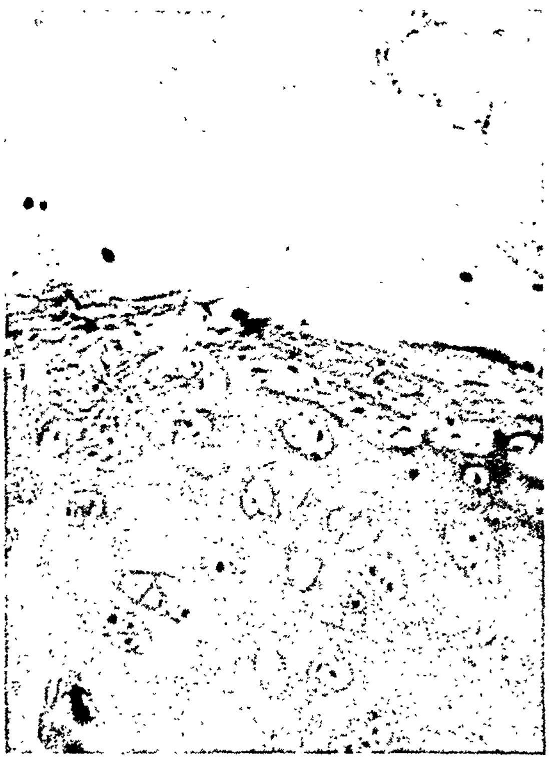

Fig. 3 (case 5).—Articular surface of arytenoid cartilage, showing destruction and disarrangement of cartilage. Roughened surface shows fibrous replacement of cartilage. Hematoxylin-eosin stain (× 125).

Collapse.—The patients presenting the most serious and dramatic cases were admitted to the hospital in a state of peripheral vascular collapse. It seems that the following sequence of events probably took place. An exacerbation occurred, usually as the result of an upper respiratory infection which augmented the existing hypoxia, with serious effects on the vital centers in the central nervous system. Clinically, this was manifested by marked restlessness. Sedation was given, and the medication inhibited the previous compensatory mechanism which had permitted the patient to suck air through the narrowed glottis. Thus a vicious cycle was established. Furthermore, the respiratory secretions, initially increased by the respiratory infection, were now retained, since hypoxia impairs both ciliary action and bronchial peristalsis. Further hypoxia may lead to coma and impairment of the cough reflex. In addition, local tissue anoxia may lead to transudation across the capillary membrane which could produce varying degrees of actual alveolar edema, augmenting further the hypoxic cycle. Finally, an infection may supervene, with the production of an extensive bronchopneumonia such as was found at autopsy in our patients who died (cases 7 and 8 in the table).

Hoarseness.—Since the vocal cords are in adduction, there is marked impairment of the airway but little impairment of vocalization. Hoarseness in these patients has always been mild, except in the presence of a superimposed, acute upper respiratory infection. It is our opinion that it is this absence of hoarseness which results in lack of attention to the actual seat of the trouble.

Diagnosis

Physical Examination.—The physical signs vary with the degree of fixation, the narrowness of the glottis, the presence or absence of acute, superimposed respiratory infection, and the therapy which has been given. In the absence of sedation or of infection, physical examination may be unrewarding. Audible inspiratory stridor is the chief sign. There is no accompanying hoarseness and little dyspnea or thoracic discomfort. While the stridor may or may not be accentuated by exertion, physical activity is impaired by exertional dyspnea. In some patients the striking finding is a history of long-term tracheostomy, with inability to remove the tracheal cannula without causing a recurrence of the stridor and even a sense of suffocation.

In the presence of superimposed upper respiratory infection, restlessness and mental confusion are the earliest signs. The stridor becomes more prolonged. Dyspnea, cyanosis, and tachycardia follow. Eventually coma and peripheral vascular collapse may occur.

The clinical picture may be confused further by the signs of bronchopneumonia. The latter tend to overshadow the importance of the basic pathological process and the therapeutic regimen may incorrectly stress the control of the infection at the cost of overlooking relief of the obstructed airway. The true diagnosis can be established by direct laryngoscopy with the "passive mobility" test described by Jackson.[7] The rigid fixation of the ankylosed arytenoid joint is strikingly different from its free, passive mobility in cases of paralysis of a vocal cord.[8]

Evidence of generalized rheumatoid arthritis may be present, although in our series, most patients (6 of 8) did not present any such findings.

Differential Diagnosis.—Once the diagnosis of a narrowed glottis has been entertained, the differential diagnosis rests between midline fixation of the cricoarytenoid joints and the presence of a bilateral paralysis of the recurrent laryngeal nerve. Major operation on the anterior neck and/or mediastinum has been known to produce such bilateral nerve paralysis. In the absence of such surgery, it has been postulated that either a central neurological lesion or a massive pathological process in the anterior mediastinum and neck may paralyze both nerves. It appears unlikely that any neurological lesion could involve both vagi exclusively and yet spare the nuclei of the glossopharyngeal, spinal accessory, and hypoglossal nerves which are in such close proximity to the vagal nuclei. Equally, it is just as difficult to visualize an intrathoracic lesion large enough to involve both recurrent laryngeal nerves without producing very obvious symptoms and signs. Therefore, in the absence of any surgical scars in the neck and anterior wall of the chest, this clinical picture is likely to be produced solely by bilateral fixation of the cricoarytenoid joint.

Treatment

Because the basic difficulty consists of an obstructed airway, the only definitive therapy is surgical.[9] In all cases, this therapy will consist of a combination of arytenoidectomy or arytenoidopexy preceded by elective or emergency tracheostomy.

Some patients are first seen because of acute respiratory distress. For these, emergency tracheostomy is essential to avoid the vicious cycle which follows the establishment of progressive hypoxia, retention of sputum, or both. For patients with bacterial infection, administration of appropriate antibiotics is of value.

Hypoxia and retention of sputum are conditions which must be alleviated as quickly and efficiently as possible. The restlessness seen in these patients is always due to hypoxia and should never be treated by the administration of sedatives which inevitably increases the patient's difficulties. Since there is no retention of carbon dioxide, therapy with oxygen can be given with safety. Retention of sputum is best treated by frequent aspiration of the retained secretions. Viscosity of these secretions can be diminished greatly by the intratracheal instillation of detergents, proteolytic enzymes, or both, followed by aspiration through the tracheostomy. After the immediate emergency has been controlled and all evidences of infection have been eliminated, definitive surgery may be performed.

It is tempting to use steroids in an effort to alleviate the acute exacerbations, because these drugs are of value in the symptomatic control of peripheral rheumatoid arthritis. In the two cases reported by Montgomery,[4a] both patients received steroids because of disseminated arthritis; yet one died of an acute exacerbation of cricoarytenoid arthritis, and the other died from acute cholecystitis with cholelithiasis and pneumonia. In our experience, steroids have been given to patients who had stridor as their sole complaint, but no improvement was seen. In other cases, similar to those of Montgomery, we have seen acute exacerbations while the patients were receiving adequate doses of steroids. In view of these observations, it is our impression at present that steroids are not of value in the control of this lesion. Indeed, because of their role in increasing susceptibility to infection, they are probably contraindicated.

Reports of Cases

Case 3.—A 56-year-old woman was admitted to the hospital with a seven-year history of attacks of dyspnea associated with a crowing noise. The attacks lasted from several minutes to many hours. During this time she noted gradually increasing exertional dyspnea, but she was still able to perform her usual chores as a housewife without difficulty. Several times she had been given tests and treated for asthma, but no relief was obtained. She had been told also that her difficulties were due to nervousness, but she had not had any psychiatric therapy.

The crowing noise, which represented her chief difficulty, occurred almost every night while she was sleeping, when she was fatigued, or after unusual exertion. The noise was said to be so loud that it could be heard in another room. On physical examination she was found to have slight respiratory distress and to make loud, crowing inspiratory noises. The remaining findings of the general physical examination were normal, and results of all laboratory studies were negative.

During the first night in the hospital she was given a barbiturate at bedtime and about one hour later was found to be semicomatose. Respiratory distress was marked, cyanosis was evident, and a loud inspiratory stridor could be heard at both ends of the long hospital corridor. In about four hours this dramatic episode subsided spontaneously. The next day, direct laryngoscopic examination revealed that both vocal cords were fixed in the midline, with a glottic chink less than 2 mm. wide. The arytenoid cartilages and the vocal cords could not be abducted passively. Again, the patient was given a barbiturate, and soon the same dramatic chain of events occurred. Subsequently, a tracheostomy was performed to establish an adequate airway.

During the next three months she was treated with steroids, but there was no change in the arytenoid fixation. The steroid therapy was discontinued, and an arytenoidectomy was performed on the left, resulting in moderate improvement in her exertional dyspnea and stridor. Two years later, an arytenoidectomy was performed on the right, and, since then, she has had complete freedom from "asthma" and dyspnea.

Case 5.—A 51-year-old housewife was admitted with a history of recurrent wheezing and "collapse." She had active rheumatoid arthritis. Five years before, she had been hospitalized because of "collapse" from which she recovered spontaneously. No diagnosis was made at that time. Three years later she developed wheezing, which was diagnosed as asthma, but both the study of and therapy for this disorder were disappointing. Six months before admission she developed marked hoarseness and became acutely dyspneic. She was hospitalized elsewhere because of rapidly developing respiratory distress, cyanosis, collapse, and unconsciousness. The collapse and coma were relieved shortly after a tracheostomy had been performed. At this time she was told that her shock was due to acute adrenal insufficiency. Later, the tracheostomy opening was closed, but this action was followed by wheezing, dyspnea, and unusual fatigue on exertion. These symptoms progressed so rapidly that she required another tracheostomy. At this time she was told that emotional factors were playing a great part in her difficulties. She was advised to have psychiatric consultation but did not accept this advice.

On physical examination, it was noted that she was wearing a tracheotomy tube. There were evidences of active rheumatoid arthritis involving the small joints of both hands, wrists, elbows, and knees. She had subcutaneous nodules over both elbows. Except for a rapid erythrocyte sedimentation rate of 57 mm. per hour (Wintrobe) a positive C-reactive protein value, and a high latex-fixation titer, results of all her laboratory studies were normal. Direct laryngoscopy revealed that the vocal cords were fixed in the midline with a glottic chink of 2 mm. The anterior two-thirds of the cords could be bowed, but both arytenoid cartilages were fixed so that abduction was not possible. At this time she refused surgical intervention, and she was given a trial of steroid therapy. This medication relieved the symptoms of the peripheral arthritis but did not affect the cricoarytenoid fixation. Subsequently an arytenoidectomy was performed on the right, resulting in relief of her symptoms. Microscopic examination of the arytenoid joint surface revealed arthritis.

Case 7.—A 47-year-old truck driver was admitted because of generalized weakness of one year's duration. Two years prior to admission he had been studied in another hospital because of weakness and dyspnea. No diagnosis was made, and his difficulties subsided spontaneously for one year thereafter. Then he noted increasing exertional dyspnea, associated with loud crowing noises. This disturbance interferred with his speech so that even his wife had difficulty in understanding him. Three months prior to admission he had an acute, severe episode of dyspnea. He was told that his distress was due to nervousness, and he had accepted this verdict so thoroughly that he now shrugged off all his symptoms as evidence that he was a nervous person. Although he had been able to continue driving a truck, his wife reported that he had been exhausted after work, dozed constantly during off-duty hours, and sometimes slept for an entire weekend except when awakened for meals. For about one month he had suffered several frightening moments when transient "spasms" of the throat made it difficult for him to maintain control of his truck.

On admission, the only positive findings consisted of minimal hoarseness and slight tachypnea. Results of all laboratory tests were normal. At 1 a. m. the patient complained of a sudden pain in the throat, and this symptom was followed by an episode of severe dyspnea which subsided in a few moments. Because of his agitation, he was given 25 mg. of promazine (Sparine) hydrochloride intramuscularly. At 8 a. m. he was found to be cold, clammy, pulseless, tachypneic, and completely unresponsive and areflexic. Shortly thereafter his breathing was stertorous, with short periods of apnea and cyanosis. The blood pressure was 60/40 mm. Hg. The administration of metaraminol (Aramine) bitartrate and oxygen restored his blood pressure to 140/90 mm. Hg. The result of a spinal tap was normal. Direct laryngoscopy revealed a mild, diffuse inflammation of the larynx. The cords were fixed in adduction. An emergency tracheostomy was done at noon, and by 11 p. m. the patient had made a full recovery, even to the point where he was able to occlude the tracheostomy tube with his finger so that he could talk. He was lucid and spoke coherently. An x-ray film of the chest at this time showed bilateral congestion and edema and probable pneumonia on the left side.

The next morning the patient became cyanotic, and the intermittent apnea recurred. His blood pressure fell precipitously, and he became unresponsive. The tracheostomy tube was functioning well, and thorough aspiration was done through it. Levarterenol bitartrate, intravenously administered hydrocortisone sodium succinate (Solu-Cortef), and large doses of crystalline penicillin were given. A mechanical respirator with chest cuirass was used to assist respiration. Nevertheless, his condition gradually deteriorated, and he died the following morning. Autopsy revealed widespread suppurative bronchitis and pneumonia and fixation of the cricoarytenoid joints in the midline.

Summary and Conclusions

It is known that the cricoarytenoid joints may become ankylosed as the result of arthritis, with resultant fixation of both vocal cords in the midline. Since this apparently benign condition (many such patients being diagnosed as psychoneurotics) presents itself in the form of a bizarre syndrome and may result in death, a careful differential diagnosis is essential. The points to be watched for are recurrent exacerbation and remission of stridor, nonresponsive asthma, and dyspnea. Finally, dramatic and sudden collapse may occur. Both careful diagnosis and treatment consisting of preliminary tracheostomy, followed by one of the various procedures for arytenoidectomy or arytenoidopexy, may prove lifesaving.

IDIOPATHIC PAROXYSMAL MYOGLOBINURIA

Capt. Paul J. Phillippi, Capt. Frederick R. Jones
and
Lieut. Col. Wilbur L. Kenoyer, (MC), U. S. A. F.

Acute attacks of muscle pain occasionally so severe as to cause pseudoparalysis, associated with the appearance of myoglobin in the urine, and due to an unrecognizable cause have been given various names of which the most frequently used is idiopathic paroxysmal myoglobinuria. We have been able to find only 37 cases reported in the medical literature.

Myoglobinuria may occur from death of striated muscle due to crushing injuries, high-voltage shock, or arterial occlusion (anterior-tibial syndrome). The reason for the myoglobinuria is easy enough to understand in such cases, but why healthy people should experience sudden attacks of muscle pain associated with the appearance of myoglobin in the urine has been a mystery since the first case was described in 1911.[1]

The following case report is presented to re-emphasize some interesting facets of the problem.

Report of a Case

A 22-year-old white male basic trainee, who had been an outstanding athlete at the University of Georgia, experienced an episode of painful, tight thigh muscles on May 6, 1959, while on bivouac training. When he attempted to "walk the stiffness out," the pain increased in severity, and he complained of inability to move his legs. Tightness and pain in the arms, shoulders, and the calves of his legs were present to a lesser degree. A few hours after the onset of the pain physicians observed no objective changes and the patient was allowed to rest overnight. The next day he noted that his urine had turned dark brown, and the thigh pain and tenderness continued. Since the pain and dark color of the urine persisted, the patient was admitted to the hospital for evaluation and treatment on May 8.

The patient was a well-developed, muscular, athletic-appearing man who appeared in mild distress from painful thighs. The vital signs on admission were all normal and remained normal throughout the hospital stay. All the muscles of both thighs were moderately spastic. The patient complained of pain on motion or palpation of the thigh muscles, especially the left quadriceps. Except for absence of the patellar reflexes, neurological examination revealed no other evidence of sensory loss or reflex change.

Admission laboratory information showed a white blood cell count of 8,527 per cubic millimeter, with a normal differential count. The hematocrit value was 47%, and the platelet count was 200,000 per cubic millimeter. The erythrocyte sedimentation rate (Wintrobe) was 36 mm. per hour, and the serum potassium level was 4.8 mEq. per liter. The plasma hemoglobin level was less than 100 mg.%, and the blood urea nitrogen level was 30 mg.%. The dark brown urine had a specific gravity of 1.020 and contained protein (1+), a few granular casts, and an occasional red blood cell, with three to five white blood cells per high-power field. There was a strongly positive benzidine reaction, and results of examinations for porphyrins with use of Watson's reagent were negative. [illegible] of the thighs and abdomen show[illegible] On the third hospital day the level of serum transaminase was 143 units and that of serum creatinine 1.36 mg.%. The total serum bilirubin level was 0.5 mg.%. Biopsy specimens of muscle taken from the left quadriceps on the second hospital day and from the right quadriceps on the fifth hospital day both revealed normal muscle.

Clinically the patient gradually improved, and his urine was grossly clear on the fifth day of illness. His urinary output remained normal, and on the 13th day of illness the urinary sediment had cleared. At this time the patient was able to undergo mild, passive exercise of the lower extremities without pain or other evidence of recurrence. Four days later the patient complained of mild thigh pain and all exercise was discontinued for two days, during which time the urine remained normal. During the remainder of the convalescent period he underwent passive exercise, and by the 30th day he was able to perform mild, active exercise without difficulty. Findings of repeat laboratory studies at this time were all normal.

Comment

The etiology of this rare disease is obviously unknown, as the name implies. It has been suggested by some[2] that a familial predisposition may exist. A relationship to progressive muscular dystrophy[3] has been mentioned, but most of these patients have no apparent familial history. Electrophoretic studies have failed to demonstrate any difference between the myoglobin of these patients and that of normal persons.[4]

Clinically the disease is characterized by a sudden onset of pain and tenderness of the muscles, most frequently in the lower extremities. The degree

---

From the Department of Medicine, U. S. A. F. Hospital, Lackland Air Force Base, Texas.

of involvement seems to vary greatly from a mild discomfort relieved by rest to a severe process which may cause "pseudoparalysis" and involve all skeletal muscles in the process.[5] The myoglobin appears in the urine within a few hours and may discolor the urine from light brown to dark red. The muscle pain and tenderness usually clear up with rest in a few days. It is rare for the muscle degeneration to be severe enough to lead to death,[5] but acute renal failure has been observed several times [6] and presents a serious threat to the patient's life.

Apparent precipitation of this disease by exercise has been reported in almost one-half of the cases, but Bowden pointed out that this has not been a factor in women. The first attack usually occurs in childhood or adolescence, although it may not occur until middle age,[5] and cases have been reported of attacks occurring as early as at 2 years of age.[7] Males are involved more frequently than females, and only one case has been reported in a Negro.[4] In most patients who have been followed up for a sufficient length of time, recurrences were observed.

The finding of benzidine-positive or guaiac-positive urine without red blood cells should lead one to suspect this diagnosis, and in association with these findings albuminuria and casts may be found. When red blood cells are found in the urine, lower nephron nephrosis should be suspected and an elevated blood urea nitrogen level with other evidence of acute renal failure should be looked for. If the plasma hemoglobin level is high enough to produce hemoglobinuria, the plasma will be discolored, as can be readily determined. Elevations in the levels of serum transaminase and creatinine have been recorded, but serum bilirubin levels have been normal.

Myoglobin differs from hemoglobin in that it has a much smaller globin fraction. Although both contain the same percentage of iron, myoglobin contains only one atom of iron compared to the four atoms in hemoglobin. The molecular weight of myoglobin is about 17,500 as compared to 68,000 for hemoglobin.[2] This accounts for the difference in the renal threshold of the two pigments (about 20 mg.% for myoglobin and 100 mg.% for hemoglobin). In most of the cases studied the definitive identification of myoglobin has been achieved by spectrophotometric means. This is a technically difficult procedure as well as one that is seldom available. Recently a method of identification by means of paper electrophoresis and a peroxide-benzidine stain [4] was described. Blondheim and co-workers [8] recently described a chemical test for screening urine for myoglobin.

In the case reported here the two muscle biopsy specimens were within normal limits; in most other cases in which muscle biopsy has been done, however, changes from swelling and patchy regression of muscle fibers to fragmentation and liquefaction have been described.[6b] These findings are limited to skeletal muscle. In cases in which acute renal failure occurred studies revealed acute tubular necrosis.

Treatment at the present stage of our knowledge is limited. Strenuous exercise should be avoided where it seems to be a precipitating factor, and rest during the acute phase of the attack is indicated. One should be aware of the possibility of acute renal failure and start treatment promptly.

Summary

A patient demonstrated several classic findings of idiopathic paroxysmal myoglobinuria. These findings included (1) acute onset of thigh pain and tenderness while exercising, (2) a feeling by the patient that he could not move his legs (pseudoparalysis), (3) the onset of dark coloration of the urine a few hours after the muscle pain, and (4) a strongly positive benzidine reaction on red cell-free urine at a time when the plasma was clear and contained less than 100 mg.% of hemoglobin.

A review of the literature on this rare disease emphasized the importance of renal complications, the probability of recurrent attacks, and the need for caution by the patient with regard to future exercise.

USE OF IPRONIAZID IN TREATMENT OF ALCOHOLICS

Julius C. Travis, M.D., San Francisco

Twenty patients with histories of alcoholism were given iproniazid during recovery from bouts of heavy drinking. Iproniazid was administered to prevent or mitigate severe mental depression that often occurs in these patients. It was considered that the hazard of the hepatotoxic effect of iproniazid was less than the hazard of suicidal attempts in patients so severely depressed. None of the patients was known to have damaged livers before treatment. Polyvalent vitamins were administered concomitantly with iproniazid to prevent peripheral neuritis and liver damage. Sixteen patients had fair to excellent reversal of depression, anorexia, and insomnia; nine required less than 100 mg. of iproniazid daily. None of the patients developed liver complications or required hospitalization. There were no attempts at suicide.

For several years medical articles have reported the value of treatment with *iproniazid* (*Marsilid*) phosphate in patients with severe depression, agitated depression, and even schizophrenic depressed catatonia, but so far no report has appeared on the use of this drug in alcoholics. Because of its specific hepatotoxic effect[1] the drug was, and apparently still is, considered dangerous for the alcoholic patient, who already may be a victim of liver disease. For this reason I at first opposed its introduction into the adult guidance center of the San Francisco Department of Public Health, where alcoholic outpatients constitute the majority of the case load. However, the availability of such an unusual medicament for treatment of depression[2] eventually posed the question of its utility in selected patients with alcoholism who had no history or current evidence of liver disease.

Severe Depression in Alcoholics

After a protracted bout of heavy drinking there follows a period of sadness, remorse, and guilt which is difficult for the alcoholic patient to tolerate. He is almost driven back to drinking but usually lives through to happier days. During this period some patients may become deeply morose, have severe anorexia and troubled sleep, and feel left out of life, unable to communicate with friends or members of their own families. They begin to consider death as the only release from a mood which inexorably grips them tighter and tighter. Sedatives do not always help, vitamins fail to stimulate appetite, and mood-elevating drugs of the ephedrine type only seem to increase their anxiety.[3] Nor will other drugs reduce the anorexia, which is often so severe that any question of eating is answered by a facial grimace indicating such repugnance, if not actual nausea, that the feeling is communicated all too well to the examiner.

If, after days and weeks of treatment the medicaments given by the physician prove fruitless, the patient most frequently resumes drinking. If he does not, he may have to be referred to a psychiatric hospital for inpatient treatment. Finally, he may commit suicide.

Another type of depression, seen after a relatively minor drinking bout, occurs in persons with average moral values and acceptable behavior who have slipped back into old habits. The patient feels deeply ashamed, worries about the visible evidence of his lack of mature control and will power, may doubt his sanity, and may entertain ideas of self-destruction. In my experience most patients of this type usually recover as easily as the first group. Ordinarily one only needs to use safe and standard medicaments, encouragement, and realistic optimism to help these patients.

A third type of patient is the one who begins to drink as an escape from depression over family troubles, loss of job, and other worries. The drinking period may be relatively short, for alcohol has a limited value in combating depression, especially if it is severe. By the time the patient sees a physician, he has sunk into a mood of despair, all his old contrivances for dealing with the problems of life have failed, and he cannot place the blame on alcohol, for it is perfectly clear that he was in bad condition before he started drinking. He may also feel guilty of being an alcoholic because of his recent behavior. Hopeless to the extreme, he speaks openly of committing suicide. If he refuses to become an inpatient, and if there is not enough time to obtain a legal commitment, he may be willing to try a few days of medical treatment.

Most of these alcoholics, even outpatients, should be seen daily and given encouragement and consolation. This also provides frequent periods of observation, so that drug therapy can be adjusted in time or other appropriate action taken.

From the Adult Guidance Center, San Francisco Department of Public Health.

Treatment of Twenty Alcoholics with Iproniazid

The danger of suicide forces the physician to consider these cases deeply; I have often wished to do more for my patients than I felt was safely possible. Finally I decided to try therapy with iproniazid in one patient with a seemingly very dangerous depression. I felt that this patient, a woman aged 45 years, would shortly destroy herself if nothing were done. Compared with this, the remote risk of liver complications seemed minimal. Even if they did develop, she might have a better chance of living with iproniazid treatment. She denied any history of liver disease and did not have a swollen or tender liver.

This woman's treatment was begun with administration of 150 mg. of iproniazid per day. The results were startlingly successful; within 24 hours she began to eat and felt better than she had in several years. This impelled me to try iproniazid therapy in a small series of five similar patients. Though none experienced the sudden recovery of the first, all but one showed good or excellent results from treatment.

TABLE 1.—*Iproniazid Therapy in Twenty Mentally Depressed Alcoholics, Without Liver Damage*

Case, No	Sex	Age, Yr.	Iproniazid, Initial Daily Dose, Mg.	General Psychiatric Diagnosis	Effect of Therapy	Notes and Remarks	Total Duration of Treatment, Wk.
1	F	45	150	Agitated depression	Excellent	Increased appetite within 24 hr.	2
2	M	39	150	Inadequate personality	Good	Insomnia persisted	6
3	F	39	150	Passive-aggressive personality	Good	Aided by psychotherapy	13
4	F	45	150	Compulsive personality	Excellent	Panic relieved in 4 days	9
5	M	49	150	Passive-aggressive personality	Fair	Lassitude persisted	8
6	F	40	150	Passive-aggressive personality	Excellent	Quick response	6
7	F	40	50	Schizophrenia, paranoid	Excellent	Quick response; psychotic became activated in 2 wk.	8
8	M	43	50	Psychoneurosis, anxiety type	Good	Still insomniac	2
9	M	39	100	Passive-aggressive personality	Excellent	Has continued use of drug	40
10	F	36	50	Psychophysiological reaction	Poor	Changed to therapy with promazine hydrochloride	2
11	M	35	50	Psychoneurosis, character disorder	Poor	Drank, drug therapy discontinued	1
12	M	42	50	Anxiety type depression	Good	Able to accept psychotherapy	18
13	M	60	50	Compulsive personality	Fair	Slow response; late in treatment improved further	7
14	M	46	50	Inadequate personality	Poor	Resumed drinking	4
15	M	39	50	Character disorder	Good	Slow change	8
16	F	67	25	Adult situational reaction	Excellent	Changed in 2 days	12
17	F	38	50	Passive-aggressive personality	Good	Enabled to begin psychotherapy	22
18	F	52	25	Psychoneurosis, character disorder	Poor	Drank	1
19	F	43	25	Passive-aggressive personality	Fair	Did not contain anxiety	10
20	M	45	50	Schizophrenia, paranoid	Fair	Increased own dosage to 100 mg./day; improved	10

Except for the first one, who left treatment after two weeks, highly pleased with the results, these patients were continued on iproniazid therapy for from 5 to 13 weeks. Then, after newspaper publicity that the drug had caused one death in our city, anxiety was produced in both patients and medical staff, and for 10 weeks no new patients were given iproniazid. But patients with severe depression continued to be seen, and again the balance between the statistically remote chance of resultant hepatitis if patients received the drug and the apparently not so remote chance of suicide if it were not used changed in favor of the drug. Fifteen additional patients accordingly were given iproniazid treatment. However, the dose was reduced to either 50 or 25 mg. per day. Pyridoxine always was given concomitantly to minimize the possibility of peripheral neuritis.

Table 1, which presents data on these 20 patients, shows that the effectiveness of treatment with iproniazid seems to be reduced as soon as the starting dosage is reduced below 150 mg. per day.

The patients listed in table 1, all presenting a state of deep depression, were treated consecutively. The sex ratio of 10:10 was purely accidental. Since the ratio in the general patient load at our clinic is roughly three men to one woman, it would seem that depression occurs three times as frequently in women as in men, although the sample in this study is too small to warrant this conclusion. The patients' age range was from 35 to 67 years, with a mean of 44.5 and a median of 42. The duration of treatment was from 1 week to 40 weeks, with a mean of 9.8 and a median of 8.5.

The initial psychiatric diagnosis (see table 1) usually was made when the patient first arrived at the clinic. Where depression was not a major consideration at that time, the diagnosis indicates presenting symptoms, signs, and history; those who arrived in a depressed state are so diagnosed.

The effect of iproniazid is recorded as excellent if there was a total reversal of symptoms of depression, anorexia, insomnia, and others. A reversal of most of the symptoms, with amelioration of others, is considered good. A fair report means some amelioration of symptoms, but of insufficient degree to be good or excellent. Responses of those who obtained no effect from treatment with the drug are marked poor. In two of the four cases so reported (11 and 18) the patients resumed heavy drinking, and treatment was stopped as too dangerous for an irrational patient already using a hepatotoxic agent—alcohol. Also, iproniazid has been reported as a potentiator of alcohol and other depressants. The third poor result (case 10) was recorded for a patient whose medication was changed inadvertently at the end of two weeks, administration of iproniazid being stopped without a note of explanation in the chart. The fourth (case 14) was recorded after four weeks and shows the only true poor result in the series, possibly due to the low dosage schedule. However, one may consider that some success was obtained even from low dosages in that the disease did not progress toward suicide, as had seemed possible if not probable.

Table 2 shows the results of treatment by sex. If good results are combined with excellent, and fair with poor, the male and female groups are comparable. A slight shift toward better results in females, however, is perceptible.

Table 3 records results of iproniazid therapy according to dosage. Generally, better results were obtained when the initial dosage was the recommended 150 mg. per day. Of the eight persons with poor and fair responses, seven received 50 mg. or less per day. Since this series was completed, I have returned to use of the higher dosage range. As soon as good effects are seen, usually in about two weeks, doses are reduced as much as possible, to 50 or 75 mg. per day.

No side-effects were observed in the group reported here. One female patient had had pitting edema of the feet and ankles prior to the use of iproniazid; the edema was controlled by administration of acetazolamide (Diamox). Edema of the feet as a side-effect of iproniazid therapy has been reported. Might this not be a psychophysiological reaction fairly common in patients with an agitated depression, with or without treatment? If the edema is only a symptom of the general illness, it could be either unaffected, improved, or worsened by administration of a drug. Banghart[4] reported objective improvement of swollen joints, skin, and muscles in his study on patients with rheumatic diseases, and the development of facial edema during iproniazid treatment which receded on withdrawal of the drug. It clearly is difficult to assess this side-effect properly. All patients in this series were given polyvalent vitamins,[5] including pyridoxine, which may explain the absence of peripheral neuropathies. In no instance was dextro amphetamine sulfate given concomitantly with iproniazid, as suggested by Kline,[6] because of our experience with addiction-prone patients.

TABLE 2.—*Results of Iproniazid Therapy in Twenty Alcoholics*

	Patients, No.		
Results	Male	Female	Total
Excellent	1	5	6
Good	4	2	6
Fair	3	1	4
Poor	2	2	4

Comment

While the number of patients surveyed in this study is small, the series involves a problem not frequently seen in extreme severity. It would seem that the data are sufficient to conclude that administration of iproniazid is beneficial in cases of alcoholism when (1) history and physical examination show patients to be free from past or present serious liver involvement, (2) the drug is given with pyridoxine, (3) the risk of drug complications is much less than that of death or extensive hospitalization, and (4) the patients are not drinking. There were no cases of hepatitis or hepatic involvement seen in this series, nor did any peripheral neuritis develop after therapy was started. There were no suicides, and no patients were sent to a hospital, although two (cases 11 and 18) were lost to the study through further drinking.

TABLE 3.—*Effect of Dosage on Success of Iproniazid Therapy in Twenty Alcoholics*

	Daily Dosage			
Results	150 Mg.	100 Mg.	50 Mg.	25 Mg.
Excellent	3	1	1	1
Good	2	0	4	0
Fair	1	0	2	1
Poor	0	0	3	1

In this series iproniazid was more effective when given in initial dosages of 150 mg. per day. Results appear to demonstrate that iproniazid is of value in the treatment of the depression seen in alcoholic patients. It also seems to have helped these patients to refrain from continued use of alcohol as a cure for their depression. It is probable that the occurrence of suicide or hospitalization (and also just plain misery) has been reduced by the use of iproniazid in these patients. Since none of the patients recorded as showing a poor result from therapy is known to have been hospitalized for depression or to have committed suicide, the case selection may have erred on the side of overprotection, for, if these patients were truly suicidal but did not kill themselves after receiving no benefit from the treatment, one could assume them to be wrongly chosen. Perhaps enough benefit was obtained to prevent suicide. However, an important point in the therapy was that all patients were told the nature of their illness, that the pills were known to produce certain side-reactions making it necessary for us to keep close track of their progress, and generally that the aim in the treatment was to help them. This bit of psychotherapy may have been sufficient to turn the tide in some. However, since of the many patients whom we were unable to handle as outpatients, some did commit suicide and some needed hospitalization for long periods, I believe that this therapy of supportive relationship is inadequate to handle all such cases of severe depression. For these patients the question of suitable drug therapy should be considered. It is hoped that the new chemical analogues of iproniazid will be safe and more rapidly effective. One of these is currently being assayed clinically and will be reported on.

Summary

Twenty patients with severe depression, all alcoholics of long standing, were given iproniazid (Marsilid) phosphate in varying dosages. Sixteen obtained fair to excellent results from this treatment. All those chosen for this treatment were shown by history and gross physical examination to be free from liver disease. None developed liver disease, committed suicide, or had to be sent to a hospital, although two patients quickly resumed drinking. The results of this study indicate that the use of a high dosage increases the effectiveness of iproniazid.

150 Otis St. (3).

The iproniazid (Marsilid) phosphate used in this study was supplied by Hoffman-La Roche, Inc., Nutley, N. J.

EVALUATION OF HUMAN FIBRINOLYSIN (ACTASE)

LACK OF FIBRINOLYTIC ACTIVITY AFTER INTRAVENOUS ADMINISTRATION IN MAN

Anthony P. Fletcher, M.D., Norma Alkjaersig, M.S., William D. Sawyer, M.D.
and
Sol Sherry, M.D., St. Louis

The effects of a preparation described as a human fibrinolysin were studied in vitro and in vivo to judge its possible usefulness in treating thromboembolic disease. The tests in vitro estimated the components of the plasminogen-plasmin and the coagulation system, and the results led to the expectation that the preparation would be ineffective as a thrombolytic agent in man. The tests in vivo consisted of the slow intravenous infusion of the preparation into six patients with various chronic diseases and the hourly determination thereafter of thrombolytic activity, plasma plasminogen and fibrinogen concentrations, and plasma euglobulin thrombolytic activity. The results yielded no evidence that the preparation enhanced the clot-dissolving ability of the plasma of patients.

Therapy for acute thromboembolic vascular disease has been only relatively satisfactory, and currently much attention is being devoted to its development. Among the newer approaches is one motivated by the novel concept that thrombi and emboli might be lysed in vivo by appropriate fibrinolytic enzyme therapy. The objective, with this form of therapy, is to impart to the circulating plasma a powerful clot-lysing ability which, when sustained for long enough periods, will effect the lysis of obstructing thrombi. The successful institution of such a controlled thrombolytic (clot-lysing) state in vivo, without hazard to the patient, could hold great promise for the therapy of thromboembolic vascular disease. (The term "thrombolysis" is used to designate a process by which preformed clots [or thrombi] are lysed. The adjective "thrombolytic" is used to describe biochemical moieties capable of producing thrombolysis. This nomenclature is clearly preferable to "fibrinolysis" and "fibrinolytic" because of ambiguities inherent in the latter terminology.)[1]

From the Department of Medicine, Washington University School of Medicine.

Investigators have favored different approaches toward the problem of inducing an in vivo thrombolytic state in man. Chief interest has focused on attempts to utilize the plasminogen-plasmin enzyme system because of its physiological role in the resolution of in vivo fibrinous deposits. Plasminogen or profibrinolysin is the naturally occurring, inactive precursor of plasmin or fibrinolysin, a proteolytic enzyme whose spectrum of activity generally is similar to, though less intense than, that of trypsin. Although, at first glance, plasmin would appear to be a most suitable agent for thrombolytic therapy, there are at least three serious disadvantages to its use. 1. Plasmin dissolves preformed clots at a slow rate. 2. Large amounts of plasmin can be rapidly inactivated by the powerful antiplasmin content of the circulating plasma. 3. Plasmin, given in large enough amounts to sustain an increased proteolytic activity in the circulating plasma, will accelerate the digestion of a variety of proteins, particularly those connected with the coagulation mechanism, and lead to a serious hemorrhagic diathesis.

Recent studies have indicated that there is a much more sensitive mechanism for thrombolysis than had been suspected. Although it had been known for some time that plasminogen is a significant component of all thrombi, being incorporated within the clot, it has only recently been recognized that the major and most rapid mechanism for clot dissolution involves the activation of plasminogen to plasmin within the interstices of the thrombus itself. This activation of clot plasminogen is mediated by a plasminogen activator, which diffuses from the circulating plasma into the thrombus. As a consequence, the clot-lysing ability of the plasma may be equated with its activator content, a view supported by the experimental evidence.[1] The use of plasminogen activators as thrombolytic agents surmounts the difficulties encountered with plasmin, since (1) it simulates the natural mechanism for rapid fibrin resolution, (2) it can operate relatively independently of circulating plasmin inhibitors, and (3) it can produce clot dissolution without increasing the general proteolytic activity of the plasma, with its attendant hazard of increased proteolysis. Thus, though some have advocated the use of plasminogen activators and others have used plasmin preparations, cogent biochemical and physiological reasons exist for preferring the use of plasminogen activators and for avoiding the use of plasmin (fibrinolysin).[1]

Regardless of approach, the basic need in the development of thrombolytic therapy is for a nontoxic agent capable of inducing and sustaining a marked, measurable, and controlled increase in the clot-dissolving capacity of the plasma. The introduction of any therapeutic agent for this purpose should be accompanied by the demonstration, in the patient, that enhanced plasma thrombolytic activity follows its administration. The fact that this objective may not be readily achieved by all fibrinolytic agents introduced for clinical use is illustrated by our studies with a preparation designated by the manufacturer as "human fibrinolysin" (Actase). This preparation recently has become commercially available and has excited considerable clinical interest.[2] Unfortunately, the assay procedure performed for its standardization is one requiring a fibrinolytic test system of an empirical and undefined nature. Such an assay procedure, although useful to the manufacturer, does not provide meaningful data for physicians interested in inducing and sustaining an active thrombolytic state in vivo. The induction of such a state requires data as to the separate concentrations of plasminogen activator and proteolytic enzyme present in the preparation to be used, and these data should be expressed in meaningful biochemical terms.

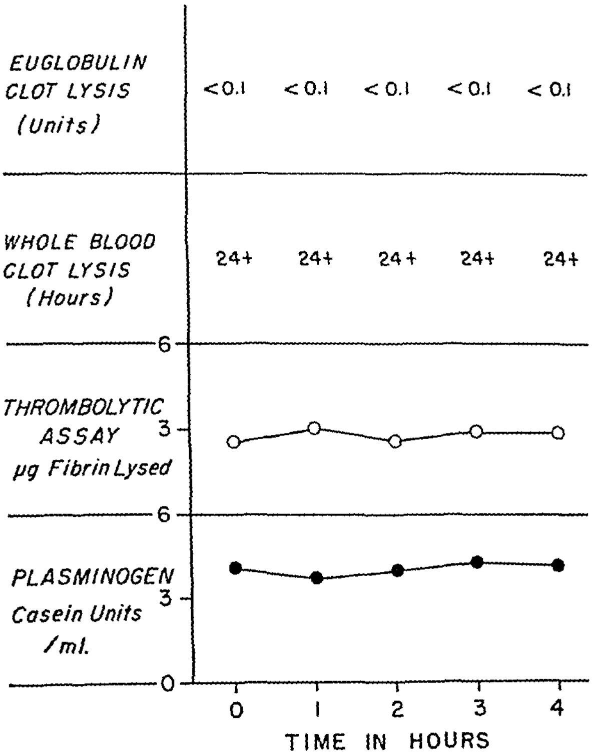
Therefore, in our studies with the human fibrinolysin we determined its composition in terms of its activator and plasmin content. On this basis, we could predict the in vivo thrombolytic activity which might be expected from its infusion[3] and then tested the validity of this prediction by infusion of this preparation (in the recommended dosage) into man. The results demonstrated that it had a composition other than that stated by the manufacturer; that, on the basis of our analysis, we could predict that its infusion into man would fail to produce specific detectable enzymatic change; and that decisive confirmation of its ineffectiveness as a thrombolytic agent was obtained by direct investigation in man.

Materials and Methods

Two different lots of the experimental substance were purchased through retail sources; samples from each lot were used for laboratory assay and then tested in patients. The methods used for assay for components of the plasminogen-plasmin and the coagulation system were as previously described.[1] The method for measurement of plasma thrombolytic activity involved assay of radioactivity released from an isotopically labeled, preformed clot which was immersed in the patient's plasma. This method provides a direct estimate of the clot (thrombus)-lysing power of plasma, and it has been refined to a sufficient state of sensitivity to allow detection of thrombolytic activity in plasma obtained from healthy, stress-free persons.[4] Physiologically relevant data are obtained, and the validity of the method is well established. Streptokinase (the plasminogen activator used in the preparation of the human fibrinolysin) was assayed by titration against specific antibody; a fibrinolytic indicator system was used, and the accuracy of the method was within ±10% limits, since a comparison of regression slopes was used in the procedure.

Results

Analysis of the product revealed the presence of both activator and plasmin. Evidence that the experimental substance was contaminated with substantial amounts of plasminogen activator (the manufacturer claims that all the streptokinase originally used is later removed) was provided by the demonstration that it readily activated bovine plasminogen, a phenomenon which could not be attributed to the enzyme, plasmin.



Effect of infusion of 50,000 fibrinolytic units of human fibrinolysin over two-hour period in 63-year-old man. No change in fibrinolytic moieties was detected.

Triplicate assays for streptokinase and plasmin were made on one vial (containing 50,000 fibrinolytic units) from each lot. One vial from the first lot contained 5.1 casein units of plasmin and 6,500 units of streptokinase. A vial from the second lot contained 3.5 casein units of plasmin and 6,750 units of streptokinase. Buffer salts were estimated to constitute 90 to 95% of the vial contents. The accuracy of the assay procedure was confirmed by mixing 5 units of human plasmin (prepared in this laboratory) with 6,500 units of streptokinase. This mixture of plasmin and streptokinase was shown to possess identical biochemical activity with regard to proteolytic and plasminogen activator assays. Thus, one vial of the human fibrinolysin contains a minute quantity of plasmin (equivalent to the quantity of plasminogen extractable from 2 ml. of plasma) and a small quantity of streptokinase.

Such in vitro assay evidence suggested that the infusion of the preparation into man (with use of the recommended doses of one or two vials) would fail to exert any detectable biochemical effect. First, the infusion of 5 to 10 plasmin units over a two-hour period into a circulatory reservoir containing 10,000 to 20,000 antiplasmin inhibitor units is unlikely to lead to any detectable biochemical change. Second, the infusion of 6,500 to 13,000 units of streptokinase over a similar period and into a circulatory reservoir containing 9,000 to 6,000,000 units of antibody (depending on the patient's state of immunization) also will prove to be unrewarding. Were there evidence that the components of the mixture exerted synergistic effects in man, such simple calculations would be invalid, but evidence of this nature is wholly lacking.

Infusion in Man.—Six patients, suffering from diverse medical conditions of a chronic nature, each received a single infusion. Four patients received 50,000 fibrinolytic units, and two received 100,000 units of fibrinolysin. The infusions were administered over a two-hour period, as recommended by the manufacturer, and blood samples for analysis were withdrawn before, during, at the termination of, and for two hours after the infusion.

The procedure used and the results obtained in a single patient are illustrated in the figure. The more important assay results obtained for the whole group are presented in the table. As is obvious from inspection of table and figure, the infusion failed to influence plasma thrombolytic activity, plasma fibrinogen or plasminogen concentrations, or the lysis time of the euglobulin precipitate. Moreover, one-stage prothrombin times, whole blood clot-lysis times, and assays for plasma antithrombin activity likewise were unaltered by the infusion. Statistical testing confirmed the impression gained by inspection, since all differences were nonsignificant ($p > 0.1$ in each instance).

Serial Observations on Fibrinolytic Moieties Before, During, and After Infusion of Human Fibrinolysin.[*]

Time, Hr.	Thrombolytic Assay, μg Fibrin Lysed	Plasma Plasminogen, Casein Units/Ml.	Plasma Euglobulin Clot Lysis, Units	Fibrinogen, Mg./100 Ml.

[*] Control specimen taken at 0 hr. Infusion period (100,000 or 50,000 units of Actase) extended from 0 to 2 hr. Mean and standard deviation of the group observations displayed; all differences not significant ($p > 0.1$).

Since the human fibrinolysin is known to produce pyrogenic effects in man,[2] the patients received aspirin prior to, and at the end of, the infusion period. Despite this precaution, three of the six patients developed chills and mild fever (with temperatures up to 101 F [38.3 C]) four to six hours later.

Comment

The attainment of control over thrombus dissolution in the vascular system would represent a major therapeutic advance. Of the many key therapeutic problems still unsolved, the control of plasma thrombolytic activity itself would seem to be the one most immediately susceptible of solution. The conceptual basis, in biochemical terms, has been most nearly accomplished, and, although practical difficulties remain, measurement parameters have been developed and a physiological approach devised.[1] Consequently, the introduction of a material such as human fibrinolysin into therapeutic use is a cause for disappointment.

We are satisfied, after review of the expanding literature on this product, that the evidence indicates that the clot-dissolving ability of the plasma has not been enhanced by the infusion of the product into patients. The meager and unsatisfactory data,[5] purporting to demonstrate such enzymatic effects, all were obtained one or more hours after the termination of the infusion, at which time the well-recognized phenomenon of plasminogen activator release secondary to any nonspecific pyrogenic response could well account for these observations. The results of the present investigation clearly indicate that, in patients, this human fibrinolysin is impotent as a clot-dissolving agent, because, in the doses recommended, it failed to increase the thrombolytic activity of the plasma. This lack of effect could have been predicted readily from a knowledge of the products composition; there is too little streptokinase or plasmin present to exceed the available antistreptokinase and antiplasmin levels of the circulating plasma. It seems reasonable to ascribe any clinical effects attributable to this agent to mechanisms other than clot dissolution.

The desire for a thrombolytic agent which can be used simply is so great that there has been reluctance to recognize the ability of the organism to inhibit these agents. The in vivo activity of all "fibrinolytic enzyme" preparations (regardless of designation) which currently are being made available by pharmaceutic firms in the United States for investigation in patients as thrombolytic agents, can be shown to depend for the most part, if not completely, on their streptokinase content. Proper use of such preparations requires knowledge of the antistreptokinase content of the plasma; this level, which may vary as much as a thousandfold among subjects, must be significantly exceeded before any thrombolytic activity can be induced in the patient. A simple test has been developed to determine how much of the preparation will be required in each case to induce such an effect. The dose required to sustain the effect may then be predicted from previous studies on the rate of clearance of streptokinase from the circulation.[3]

Summary

The aim in the development of fibrinolytic agents for the therapy of thromboembolic disease is to induce in the plasma of patients an enhanced thrombolytic activity which can be sustained, without hazard, for long enough periods to effect the resolution of obstructing thrombi. Recent evidence indicates that this desired state can be more readily accomplished with plasminogen activators than with plasmin (fibrinolysin). That fibrinolytic agents introduced for clinical use may not prove active in vivo is illustrated by studies on human fibrinolysin (Actase). This preparation, in the recommended dose, failed to enhance the clot-dissolving ability of the plasma of patients. Analysis of samples of this product revealed that each vial contained small quantities of streptokinase and human plasmin in amounts insufficient to produce any significant thrombolytic activity in vivo.

SUBUNGUAL HEMORRHAGE IN PAN WASHERS

Peter I. Long Jr., Dayton, Ohio

The purpose of this study was to determine the factors involved in an occupational affliction of kitchen workers, namely a soreness of fingers with extravasion of blood under the finger nail. Forty volunteer subjects scrubbed pans under standard conditions with a variety of detergents, and comparisons were made between one hand which was bare and the other hand which was gloved, a small amount of the detergent solution being placed in each glove. A typical subungual hemorrhage with soreness was produced in the gloved hand of one subject. At its height the lesion resembled a traumatic hematoma. Eczematoid dermatitis occurred in six subjects but involved both gloved and ungloved hands in every case. No differences were found among the detergents used. Gloves should be worn for prolonged, repeated pan washing, and the washing solution should not be allowed to accumulate inside the gloves.

After the report of three cases of subungual hemorrhages which occurred among the pan washers at the Veterans Administration Center, Dayton, Ohio,[1] a series of clinical studies were formulated and carried out, which, it was hoped, would further elucidate the pathogenesis of these lesions. From the original studies it was felt that the primary etiological factors were the pH of the washing solution trapped inside the washers' gloves and the trauma of scrubbing.

Method

The study was conducted with a group of 40 volunteers from the domiciliary section of the center. The subjects were men between 46 and 70 years of age. About one-third of the subjects were Negroid. Each member of the group was patch-tested for sensitivity to detergent and rubber prior to the beginning of the study. None of the men of the group demonstrated any sensitivity after 24 or 48 hours when the patches were removed.

The men were then divided into groups of five, and each group was assigned a specific cleaning agent and washing procedure. Each man wore a rubber glove on one hand and kept the other hand bare. Each glove was kept filled with a small amount of the washing solution used. In all experiments the water temperature was maintained between 100 and 112 F. The pH was kept between 7.2 and 9. To simulate actual pan room scrubbing conditions as nearly as possible, it was decided to have the men scrub on corrugated metal boards, so small washboards were used. Several times each day the boards were coated with sugar which was heat-melted on the metal. This gave the men something to clean and made effort requisite, causing trauma to the hands. The men were constantly observed and required to scrub for about equal periods of time with the gloved and ungloved hand. The scrubbing was done with standard gauge steel wool obtained from the kitchen. Each group scrubbed for three hours a day for a total of 10 days, Saturday and Sunday being omitted. Photographs of each man's hands and nails were taken before and at the conclusion of the study. All specific lesions developing on the hands or under the nails were photographed immediately when noted.

Washing solutions assigned to each five-man group were as follows: group 1, liquid detergent 1; group 2, liquid detergent 2; group 3, powdered detergent 1; group 4, powdered detergent 2 (a product being used in the hospital); group 5, powdered detergent 1 and pan drippings; group 6, powdered detergent 2 and pan drippings; group 7, pan drippings; and group 8, water (control).

Water was added to each substance tested as a dilutant. The detergents were diluted according to instructions given by the manufacturer for the various products.

The pH of the glove solution varied from 7.2 to 7.6 in this series. In none of our experiments were we able to reduplicate the acid condition of the solution trapped in the gloves of the pan washers in the hospital kitchen which ranged in pH from 4.5 to 7. All types of skin lesions, as well as nail bed pathology, were recorded. Hands were examined each day at the beginning and at the end of the three-hour period of scrubbing.

One substance, a powdered detergent, composed of sodium sulfate and alkyl arylsulfonate, was injected by hypodermic needle beneath my own nails in the following manner. A 22-gauge needle was slowly inserted beneath the nail, bevel down, to a depth of 0.25 in., and about 0.1 to 0.3 cc. of test solution was injected. Every attempt was made to make this as atraumatic as possible.

The following test solutions were prepared from this detergent and injected: (1) sodium sulfate; (2) the detergent (composed of sodium sulfate and alkyl arylsulfonate) in water; (3) sodium sulfate and grease; and (4) alkyl arylsulfonate and grease. Additional tests performed one month later involved solutions of sodium sulfate and alkyl arylsulfonate heated to 110 F. These solutions were injected into the first and second fingers of the left

hand. No other direct subungual inoculations were attempted, since we were unable to obtain volunteers who would submit to the injection.

Results

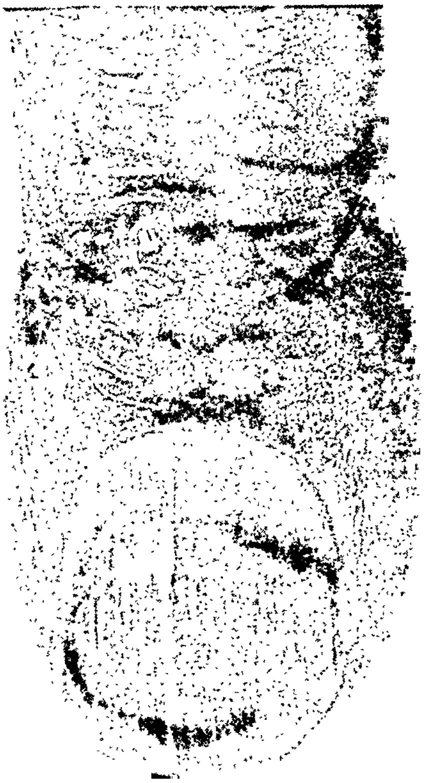
During the course of this study, we reproduced, under controlled conditions, one typical subungual hemorrhage, as described in the original report.[1] The case is reported here in detail. Four types of reaction of the skin of the hands were noted during this experiment—dryness, maceration, dyshidrosis, and eczema. Every subject exhibited maceration of the skin of both hands, usually slightly worse on the gloved hand. Each day this subsided within several hours after the scrubbing was stopped. There was a slight drying and cracking of the skin in practically all subjects, but it was not considered disabling. There were six cases of eczematoid dermatitis, three of which were severe enough to warrant the removal of the men from the experiment. In each instance both the gloved and ungloved hands were involved. The men presented erythema, vesicle formation, and weeping lesions, which appeared first on the fingers and then spread to the dorsum of the hands. In none of these cases were the nail beds involved.

One case was classified as dyshidrosis. The subject developed small multiple white papules on both hands, on the dorsal as well as the ventral surfaces. These would disappear within two hours after the subject ceased scrubbing. They could be reproduced by merely soaking the hands in water for two hours at a temperature of 90 F. Subungual injection of the test substances described above did not produce any significant lesions in one subject.

Report of a Case

A 70-year-old man was placed in group 5 to scrub with a solution that consisted of powdered detergent, water, and pan drippings. He scrubbed on a corrugated board. The right hand was gloved and the left hand was ungloved. The water temperature was 110 F, and the pH ranged from 7.2 to 7.6. The subject's general health was good. He never had had skin disease or any disease involving the hands or nails.

On the second day of exposure, the subject complained of soreness under the nail of the third finger of the gloved hand. On examination at this time there was a blush on the distal one-third of the nail bed, and it was tender on pressure. There was no evidence of laceration or separation of the nail from the nail bed. At the end of scrubbing on the third day a small bluish colored area, about 5 mm. in diameter, was noted on the lateral portion of the nail bed, two-thirds the distance from the nail base. On the fourth day the man continued to scrub; however, he complained of soreness and had to guard the finger while scrubbing. On examination, the distal one-third of the nail bed was tender to pressure and red in appearance. Since the next days were Saturday and Sunday, no scrubbing was done. However, on Monday, prior to his beginning to scrub, the man's finger presented a typical picture of the subungual hemorrhages previously described. The nail bed was fiery red, and multiple small, punctate, dark, hemorrhagic areas were scattered throughout. The man was stopped from participating in the experiment but was examined daily. The bleeding points coalesced, and in several more days the finger showed the appearance of a traumatic hematoma of the nail. In about one month's time the distal one-third of the nail had separated from the nail bed and was removed. Four months later the nail had not recovered the distal one-third of the nail bed. This man would not permit subungual injection by hypodermic of the component substances of the solution in which he was scrubbing.



Maximum extent of fingernail lesion in subject in case 1.

Comment

One case of subungual hemorrhage was produced in 40 attempts and occurred under conditions which simulated the actual conditions in a pan washing room. This hemorrhage occurred on the gloved hand. The glove contained a mixture of warm water, a powdered detergent, and kitchen grease. It occurred under conditions conducive to trauma and developed within three days after exposure. The pH of the solutions seemed unimportant since in this instance the pH of the glove and the pan solution remained equal, varying from 7.2 to 7.6. The subungual injection of the component parts of the detergent and solution in which this man scrubbed did not produce subungual hemorrhage in another subject.

From the experiments described, the mechanism of these hemorrhages may be explained as follows. The washing solution trapped in the gloves softens the skin and subungual tissue, and the trauma of scrubbing probably causes small breaks between the nail and the nail bed. The detergent solution and grease is forced into the subungual tissue by pressure on the water trapped inside the glove. These substances then produce hemorrhage in the subungual tissue in a susceptible person. Trauma alone cannot account for the changes observed, since the lesions progressed after the person was removed from the source of trauma.

Summary and Conclusions

Forty volunteers were subjected to experiments planned to produce subungual hemorrhages. A subungual hemorrhage was successfully produced in one subject under conditions simulating those found in actual pan scrubbing. Clinically, the lesion described progressed from erythema to hemorrhage and at its peak had the appearance of a traumatic hematoma.

No specific etiological agent was identified. Injections of suspected substances subsequently produced no hemorrhages in one subject. In these experiments there resulted six cases of eczematoid reaction of the hands, half of which were considered disabling.

Pan washers should wear long, cuffed, watertight gloves to prevent the accumulation of washing solution in contact with skin surfaces.

TREATMENT OF MALIGNANT PLEURAL EFFUSIONS BY TALC POUDRAGE

George J. Haupt, M.D., Rudolph C. Camishion, M.D., John Y. Templeton III, M.D.
and
John H. Gibbon Jr., M.D., Philadelphia

The operation of talc poudrage here described is designed to stop persistent pleural effusions in cases of incurable cancer. The incision permits exploration of the affected hemithorax and can be extended if the lesion is found to be resectable. If it is not resectable, the pleural surfaces are generously dusted with sterile talc (USP) and two fenestrated intercostal drainage tubes are inserted through separate stab wounds; the latter permit application of suction to maintain complete obliteration of the pleural space for 48 to 72 hours. Two cases are described in detail, and the results of 19 operations are described. Thirteen were for primary pulmonary neoplasms; three were for metastatic carcinoma of the breast. In every instance dyspnea was relieved and recurrence of the effusion was prevented. There were no complications or deaths attributable to the operation.

The treatment of persistent pleural effusion due to incurable cancer is a difficult problem. The effusion is usually due to involvement of the pleura by the neoplastic process, but it may result from extensive lymphatic obstruction or inflammatory reaction secondary to a tumor within the lung. Dyspnea may be severe; it results from compression of the ipsilateral lung by the fluid and the contralateral lung by shift of the mediastinum. The pleural fluid contains not only electrolytes but proteins, leukocytes, and a varying concentration of erythrocytes. Early recurrence of the effusion after aspiration usually necessitates increasingly frequent thoracenteses, which debilitate the patient.

A variety of techniques for obliteration of the pleural space have been proposed. In 1906, Spengler[1] instilled silver nitrate into the pleural space of patients with spontaneous pneumothorax of tuberculous origin. He later used glucose to induce obliterative pleuritis.[2] The introduction of other irritating substances for the purpose of producing pleural symphysis has also been reported.[3] Parietal

pleurectomy as a method of producing permanent pleural symphysis was described by Gaensler[4] and later by Thomas and Gebauer[5] for the treatment of recurrent and chronic pneumothorax. The instillation of radioactive gold colloid has been advocated for the treatment of malignant pleural effusions. It is effective in preventing recurrence of the effusion in only 30 to 50% of patients.[6]

In 1935, Bethune[7] first reported the use of talc poudrage as a preliminary procedure to lobectomy. Medici[8] and later Meade and Blades[9] and Smith[10] reported the use of this method in the treatment of recurrent and chronic pneumothorax. Pulmonary function studies made after obliteration of the pleural space by talc poudrage have been reported by Paul and others[11] and Knowles and others.[12] No permanent ventilatory impairment was demonstrated.

The purpose of this paper is to describe the results obtained from the use of talc poudrage in the treatment of 19 patients with pleural effusion secondary to irremovable cancer. The procedure was well tolerated and attended with no significant morbidity. Dyspnea is not a contraindication, since the prevention of the effusion improves ventilation. Biopsy can be done at the time of operation. It is immaterial whether the malignant process is one arising from a primary intrathoracic tumor or whether it has resulted from pleural involvement secondary to a neoplasm originating outside of the thorax.

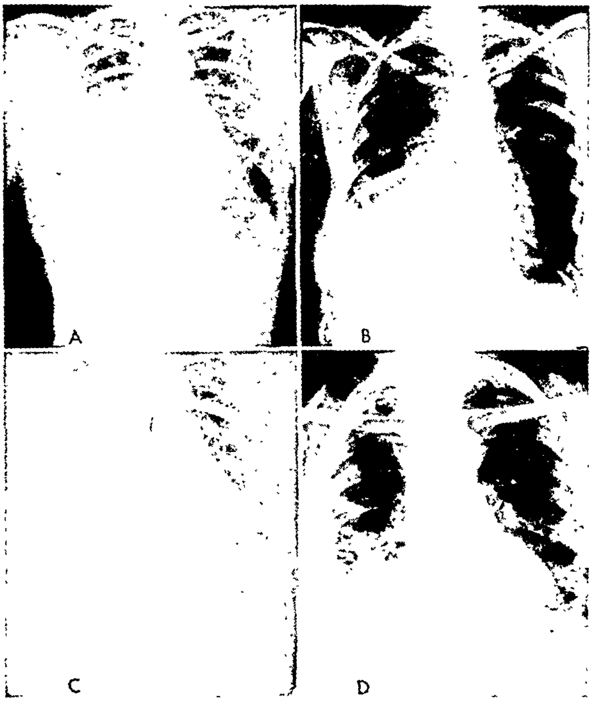
Technique and Procedure

With the patient lying on his side under light endotracheal anesthesia an oblique incision, 4 to 10 cm. in length, is made in the infra-axillary region. The pleural space is entered through the bed of a short segment of resected rib or through an interspace, usually the sixth or seventh. All free and loculated fluid is removed and exploration is carried out. The presence of noncontiguous pleural metastasis or other indications of nonresectability can be established quickly and a biopsy sample for frozen section can be taken. Should the lesion prove to be resectable, the incision may be extended and converted into a standard posterolateral thoracotomy. When nonresectability is established, the pleural surfaces are generously dusted with sterile talc (USP) and two fenestrated intercostal drainage tubes are inserted through separate stab wounds into the pleural space. The lung is gently inflated under direct vision. In some instances, it is necessary to decorticate an area of the underlying lung to permit complete obliteration of the pleural space. The incision is closed and sufficient suction is applied to the drainage tubes for 48 to 72 hours to insure complete obliteration of the pleural space.

Report of Cases.—The following two brief case reports are presented as examples of the application of this procedure. One patient had pleural effusion secondary to metastatic carcinoma of the breast and the second had effusion due to bronchogenic carcinoma.

CASE 1.—A 30-year-old woman was admitted to Jefferson Medical College Hospital on Dec. 22, 1956. She complained of progressively severe dyspnea of two months' duration. Two years previously a simple mastectomy on the left had been performed for medullary carcinoma of the breast.

A right pleural effusion was present (see figure, *A*), from which 800 ml. of straw-colored fluid was aspirated. No acid-fast bacilli or neoplastic cells were found. After thoracentesis, x-ray examination of the chest revealed no lesion of the lungs. Bronchoscopic examination was negative. On Dec. 27, 1956, the right pleural space was explored through a small incision and about 1 liter of straw-colored fluid was removed. Many pleural nodules of anaplastic carcinoma were present. Talc poudrage was carried out, as previously described. The intercostal drainage tubes were connected to a source of negative pressure for 48 hours. The patient's postoperative course was uneventful and she was discharged from the hospital on the eighth postoperative day, free of symptoms. She survived for four months without dyspnea or recurrence of the pleural effusion (see figure, *B*).



Top (case 1), *A*, preoperative roentgenogram of chest made Dec. 22, 1956; *B*, postoperative roentgenogram of chest made Jan. 4, 1957, showing improvement. *Bottom* (case 7), *C*, preoperative roentgenogram of chest made July 30, 1957; *D*, postoperative roentgenogram of chest made Aug. 20, 1957, showing improvement.

Case 7.—A 67-year-old man was admitted to Jefferson Medical College Hospital on July 30, 1957, with the chief complaint of dyspnea. He had lost 50 lb. (22.7 kg.) in weight during the previous three months. A massive pleural effusion was present on the right (see figure, *C*). On Aug. 1, 1957, 4 liters of bloody fluid was removed. No neoplastic cells or acid-fast bacilli were found and bronchoscopic examination showed normal findings. Thoracenteses on Aug. 6 and again on Aug. 12 were productive of 2,500 ml. and 2,100 ml., respectively, of bloody fluid. A histological diagnosis could not be established, and his condition was steadily deteriorating. On Aug. 16, 1957, with the patient under light endotracheal anesthesia, the right pleural space was explored through a small incision and 2,500 ml. of bloody fluid was removed. Both the visceral and the parietal pleura were found to be studded with nodules. Frozen section of one of the nodules was reported as "poorly differentiated carcinoma involving the pleura." Talc poudrage was performed, intercostal drainage was established, and the lung was reinflated. The intercostal drainage tubes were removed on the second postoperative day. The patient was discharged on the eighth postoperative day. There was no recurrence of dyspnea or of pleural effusion during the remaining 13 months of his life (see figure, *D*).

Results

Nineteen consecutive patients with persistent pleural effusion resulting from primary or metastatic intrathoracic cancer have been treated by talc poudrage (see table). The relief of dyspnea, prevention of recurrent accumulations of fluid, and palliation afforded have been striking. There was no operative mortality and no operative complications occurred. The average hospital stay was 10 days. Of the 19 patients 11 were men. Ten had primary carcinoma of the lung and one had a malignant mesothelioma. In six of the eight women the primary tumor was extrathoracic. Two women had primary carcinoma of the lung. The progress of all patients has been followed to the time of writing or until death. The longest period of follow-up is 26 months. There has been no recurrence of the pleural effusion in any case. Of the 19 patients 5 are living, at the time of writing, from 1 to 26 months after operation. Of the 19 patients 14 have died of their primary disease. The survival time of these patients ranged from 2 to 13 months, with an average of 6 months. All patients were relieved of their preoperative dyspnea.

*Summary of Case Data in Nineteen Patients Treated by Talc Poudrage**

				Operation		
No.	Age, Yr.	Sex	Diagnosis	Date	Type	Survival Time, Mo.
1	30	F	Metastatic carcinoma of breast with right pleural effusion	12-27-56	Right talc poudrage	4
2	59	F	Carcinoma of left lung with left pleural effusion	5-24-57	Left talc poudrage	13
3	57	F	Metastatic carcinoma of breast with left pleural effusion	6-29-57	Left talc poudrage	6
4	53	M	Carcinoma of left lung with left pleural effusion	7-3-57	Left talc poudrage	6
5	66	M	Carcinoma of right lung with right pleural effusion	7-21-57	Right talc poudrage	2
6	61	F	Metastatic hypernephroma with right pleural effusion	7-31-57	Right talc poudrage	26†
7	67	M	Carcinoma of right lung with right pleural effusion	8-16-57	Right talc poudrage	13
8	52	M	Carcinoma of right lung with right pleural effusion	8-22-57	Right talc poudrage	10
9	56	M	Anaplastic carcinoma of right lung with right pleural effusion	12-9-57	Right talc poudrage	2
10	72	M	Carcinoma of right lung with right pleural effusion	12-11-57	Right talc poudrage	3
11	63	M	Carcinoma of right lung with right pleural effusion	12-31-57	Right talc poudrage	2
12	59	M	Carcinoma of left lung	4-25-58	Left talc poudrage	8
13	64	F	Metastatic malignant thymoma with right pleural effusion	5-5-58	Right talc poudrage	5
14	55	M	Carcinoma of right lung with right pleural effusion	6-16-58	Right talc poudrage	3
15	65	F	Metastatic carcinoma of breast with right pleural effusion	8-12-58	Decortication and right talc poudrage	2
16	48	M	Anaplastic carcinoma of right lung with right pleural effusion	8-22-58	Right talc poudrage	12†
17	37	F	Carcinoma of right lung with right pleural effusion	11-12-58	Right talc poudrage	9†
18	51	F	Metastatic rhabdomyosarcoma with right bronchopleural fistula, empyema, trapped lung	6-12-59	Right lower lobectomy; decortication, right upper and middle lobes; talc poudrage	2†
19	60	M	Malignant mesothelioma with right pleural effusion	7-13-59	Right talc poudrage	1†

* There were no recurrent effusions in the series

† Living at time of writing (Aug. 15, 1959).

Summary

In 19 patients with persistent pleural effusion due to cancer, talc poudrage prevented recurrence of the effusion in every instance. No deaths and no complications were attributable to the operation. Gratifying relief of dyspnea was obtained in every case.

INITIAL CLINICAL REACTION TO THERAPEUTIC WHOLE-BODY ROENTGEN RADIATION

SOME CIVIL DEFENSE CONSIDERATIONS

William C. Levin, M.D., Martin Schneider, M.D., Galveston, Texas
and
Herbert B. Gerstner, M.D., San Antonio, Texas

The effects of whole-body roentgen radiation were studied in 11 patients with far-advanced neoplastic disease in order to form a picture of the typical initial response to ionizing radiations. The nominal air dose was 150 r in seven patients and 200 r in four. At this dosage level the duration of the latent period and intensity of ensuing symptoms were determined more by personal differences than by amount of radiation. During the "delay period" of one or two hours there were no symptoms. Two patients later experienced nausea, and two others remained asymptomatic. In the remaining seven, fatigue and apathy appeared abruptly from one hour to four and one-half hours after the irradiation. The onset of vomiting sharply marked the beginning of the initial reaction, which reached its climax five to eight hours after irradiation and then steadily receded. Evidently, among large groups of people exposed to radiation from a nuclear weapon, many who are capable of self-help during the first hour will become prostrated during the three hours that follow.

Medical application of Roentgen's discovery of the "x-rays" soon led to the observation that cancericidal doses of the new agent frequently elicited an early systemic reaction characterized by dizziness, fatigue, anorexia, nausea, and vomiting. This clinical complex—termed "radiation sickness"—developed into a more and more serious problem as the intensity and penetration of therapeutic radiation increased with the technical advancement of x-ray equipment.[1] The radiotherapist then learned to minimize the irksome side-effects by dividing the total dose into fractions delivered at intervals; the size of each fraction and the length of intervals between exposures were determined by the patient's disease and general condition. This procedure, together with closer restriction of radiation to the tissue volume intended for treatment, proved so effective that radiation sickness lost its significance for modern radiotherapy.

Renewed interest in the early clinical reaction, however, arose with the advent of the atomic age. Ever-accelerating use of nuclear energy, for military and industrial purposes alike, created the hazard of deliberate or, to a lesser degree, of accidental disasters exposing large populations to significant amounts of penetrating radiation. Under these

---

circumstances, the early clinical sequelae that constitute the initial reaction to such exposure have left the realm of radiotherapy and have entered a sphere of concern to all physicians who, in an emergency, might be confronted with radiation casualties. This atomic age also brought about the need for more precise terminology, based on the time relationship between the various phases in the clinical response to penetrating radiation. To specify the early burst of signs and symptoms, the broad term radiation sickness should be replaced by the more restricted and more striking denotations "initial" or "prodromal" reaction.[2]

Although it has been almost eliminated as a complication of routine therapy, the initial reaction still can be seen and studied in the rare patients who require treatment with single high doses to the entire body.[3] Observations on such patients merit particular interest because they are the only human samples for whom type of radiation, dose distribution, and total dose are known with certainty; therefore, they are indispensable for establishing correlations between physical parameters and the clinical consequences of radiation. On the basis of 11 case histories, the present report describes the early radiation-induced response and evaluates its potential role in nuclear disasters.

TABLE 1.—*Data on Patients Treated with Whole-Body Roentgen Radiation*

Patient, No.	Sex	Age, Yr.	Diagnosis	Nominal Air Dose, r	Start of Radiation; Time of Day
1	F	62	Hodgkin's disease	150	0915
2	M	57	Adenocarcinoma	150	1235
3	F	61	Hodgkin's disease	150	1115
4	M	39	Hodgkin's disease	150	0930
5	M	69	Giant follicle lymphoma	150	1200
6	F	15	Ewing's sarcoma	150	1310
7	M	5	Acute lymphocytic leukemia	150	0930
8	M	48	Carcinoma of kidney	200	1010
9	M	13	Malignant lymphoma	200	0900
10	M	25	Lymphosarcoma	200	0930
11	M	52	Malignant lymphoma	200	0900

Method

Previous studies[4] had shown that whole-body irradiation might be a tool for inducing palliation, or even temporary remission, in patients with cancer inaccessible to more promising kinds of treatment. Accordingly, the 11 patients selected for the present series suffered from malignant neoplasms that were so widely disseminated and so far advanced—predominantly stage 3 lymphomas of various histological types (table 1)—that any other mode of management appeared hopeless. The antecedent clinical history varied; in most instances, records revealed futile attempts at controlling the disease by local roentgen radiation, by steroid administration, or by chemotherapy.

Hospital admission preceded irradiation by at least one week; during this period each patient was seen daily by the same resident physician who, in addition to the usual examinations, recorded activity, behavior, and mental attitude. Seven of the patients were in relatively good general condition; they had permission to walk freely about the ward and to participate in moderate physical activities. For the remaining four, however, confinement to bed was necessary because of weakness, weight loss, and a tendency toward nausea and temperature elevation. The one-week adaptation phase was followed by the radiation treatment and then by a postexposure period of observation usually exceeding 10 days. At all times, even on the day of treatment, the initially established routine was maintained—examination by the same physician, normal meal schedule, and liberty of movement for ambulant patients. Administration of radiation, as a rule, occurred during the interval between breakfast and lunch (table 1); only occasionally did antiemetic treatment appear indicated.

The radiation source was a conventional roentgen ray apparatus operated under the following conditions: 250 kvp; 30 ma.; filtration added to beryllium window of tube, 1 mm. aluminum and 0.5 mm. copper; half-value layer, 1.2 mm. copper; open portal; and distance from target to midcoronal plane of the patient, 200 cm. At that distance, the dose rate in air averaged 9 r per minute. Multiplication of this value by exposure time yielded the "nominal air dose"[5] that was adopted for dosimetry throughout this analysis. As verified by radiographic check-films, the entire body remained well within the primary beam directed horizontally toward the patient who, with hips and knees flexed, lay on his side on a treatment table. First, facing the x-ray machine, each received one-half of the prescribed dose; then, presenting their posterior aspects to the source, they received the remaining half-dose. In this manner, whole-body doses of either 150 or 200 r (table 1) were administered during a single session of about 20 or 25 minutes respectively.

Results

As its most striking feature, the initial reaction displays wide variability among persons exposed to similar, or even identical, doses. The present series corroborated previous findings,[3] symptoms in patients ranging from complete absence to severe prostration. This dramatic individual difference of unknown origin, together with the difficulty of assessing complications possibly caused by the preradiation disease, renders the group of 11 patients much too small for derivation of a typical clinical picture. Yet, from a comparison of present findings with previous reports on early consequences of both therapeutic[3] and accidental[2b] whole-body exposure, the characteristic initial reaction emerges with reasonable accuracy.[6]

Typical Clinical Picture.—Throughout the time of exposure, radiation induces no sensations and the patient remains completely asymptomatic. After completion of treatment, this freedom from symptoms continues for about one or two hours–the "delay period."[8] Then, rather abruptly, the reaction starts with the onset of fatigue, listlessness, and apathy. Usual activities are discontinued; lying down on his bed, the patient withdraws more and more from his environment and appears depressed. Not infrequently, he describes his condition as "washed-out" or "worn-out," and complains of dizziness, dulness, and headache. This "fatigue complex"[7] is accompanied as a rule by concurrently developing signs and symptoms pointing to the gastrointestinal tract. Loss of appetite and complaints about an "upset stomach" suddenly occur around two hours after exposure. Nausea, frequently associated with spells of frank vomiting, soon supervenes and increases in intensity until it reaches a climax somewhere between five and eight hours after irradiation. At that time, the combination of "fatigue complex" and "vomiting complex" may lead to pronounced weakness or even to prostration.

After passage through the climax, the reaction steadily recedes; intervals between bouts of vomiting lengthen, emeses decrease in number as well as in volume, until they disappear completely. Nausea, anorexia, and fatigue then subside in that order. Because of the gradual ebbing of the succession of exacerbations and remissions, the duration of the initial reaction cannot be defined accurately, but the usual course is as follows: On the second day, moderate nausea and occasional spells of vomiting still persist but the general condition is markedly improved; on the third day, the patient becomes asymptomatic.

Special Observations.–To fathom its potential impact on populations engulfed by nuclear disasters, the initial reaction demands special analysis from two aspects–length of delay time and extent of disability.[8] Length of delay time, obviously, is important because the interval between radiation exposure and the onset of clinical symptoms represents the period during which an exposed group remains in full possession of physical fitness and mental alertness–faculties so vitally necessary for well-organized active evacuation of disaster areas. The extent of disability, on the other hand, requires careful consideration because of its significance when evacuation cannot be executed or completed within the delay time; the initial reaction, unfolding among members of the afflicted population, will impair capabilities for active participation in escape, rescue, and other emergency efforts. Again, for a reasonably accurate assessment of these two important factors, the present findings are insufficient and must be supplemented by previous studies.[9]

Civil Defense Considerations

The delay time is known most reliably for patients who experience reactions leading to vomiting. Owing to its occurrence shortly after onset of symptoms, the first emesis strikingly and dependably marks the beginning of the initial reaction and is thereby indicative of the length of the delay period. That this period has a characteristic duration is strongly suggested by comparing, in table 2, the following sets of evidence: first, the present findings; second, a part of the results of Miller and co-workers[3]–of 30 patients exposed to 200 r, observations are presented only for those who vomited during the first 24 hours after treatment; and third, data reported for the Y-12 accident.[9a] Most conspicuously, the table demonstrates three points: (*a*) when vomiting develops at all during the day of exposure, the initial emesis consistently occurs in the interval starting at one hour and ending at five hours after radiation; (*b*) in the several-hundred-roentgen range, length of the delay period is barely affected by dose; and (*c*) agreement between therapy and accident data suggests irrelevance of radiation type (roentgen, gamma, neutron, or any mixture of these penetrating rays).

TABLE 2.–*Delay Time Elapsing Between Start of Whole-Body Irradiation and Onset of Vomiting on Day of Exposure*[*]

	Cancer Patients					
	Present Series		Miller[3] Series		Healthy Persons	
Patient No.	First Emesis, Hr. After Treatment	Air Dose, r	First Emesis, Hr. After Treatment	Air Dose, r	First Emesis, Hr. After Exposure	Body Dose, rad
1	nausea only	150	2.0	200	2	365
2•	4.5	150	2.0	200	4	270
3	nausea only	150	2.0	200	asymptomatic	339
4	*asymptomatic*	150	3.0	200	2	327
5	3.3	150	3.0	200	nausea only	236
6	1.0	150	3.5	200		
7	3.5	150	4.5	200		
8	1.8	200	5.0	200		
9	1.5	200				
10	2.5	200				
11	asymptomatic	200				

[*] Observations on patients in the present series and that of Miller and co-workers[3] are compared with data from healthy persons involved in typical nuclear accident.[9]

The validity of the three points has been established by a comprehensive analysis covering additional therapy evidence and all known nuclear accidents.[6] Hence, it must be anticipated that a population exposed to radiation in the several-hundred-roentgen range will remain completely asymptomatic for one hour and will experience a negligible incidence of initial reactions during the ensuing hour. Consequently, for all practical purposes, the two-hour time limit represents the delay period applicable to a large group of persons, because, after transgression of this limit, the incidence of prodromal reactions rapidly reaches a maximum between the fourth and fifth hours after exposure. That, occasionally, vomiting may start on the second or even the third day has been reported for all groups–radiotherapy patients, persons involved in nuclear accidents, and Japanese bomb casualties; these rare, atypically timed manifestations probably can be explained as reactions to psychological stresses or to other complications.[6]

Disability.–Among members of the present series, there was extraordinary variation in disability, with respect to both extent and duration. Two patients remained completely asymptomatic and, obviously, retained full possession of capabilities existing prior to exposure. In two other patients, the reaction assumed the form of a mild indisposition characterized by fatigue, anorexia, and episodes of nausea, headache, and dizziness. Even during the period of definite discomfort, generally commencing about two hours and subsiding about eight hours after exposure, almost any degree of activity probably could have been performed if necessary.

Quite a different appraisal of the initial reaction, however, was necessary for the seven patients who developed vomiting. During the most intense phase, usually extending from the 2nd through the 10th hour after radiation, prodromal effects distinctly impaired their mental and physical capabilities. This impairment, caused by the combination of apathy and depressed mood with weakness and malaise, attained such a degree in four of the patients as to seriously hamper their execution of any task demanding more than well-drilled actions. In these instances, the clinical impression suggested that disability had progressed too far to be overcome, or decisively alleviated, by psychological factors–probably not even by the strong motivations inherent in disaster situations. Such a conclusion could be drawn beyond any doubt for one patient who, throughout 24 hours, experienced complete prostration and inability to walk. Thus, extent of disability among the 11 patients covered the entire scale from unnoticeable impairment to absolute physical incapacitation; when disability occurred, it prevailed mainly during the interval starting about 2 and terminating about 10 hours after exposure. How do these findings compare with previous data?

Comparison of the present series (G) with both the group studied by Miller and co-workers[3] (M) and the Y-12 patients[9] (Y) yields the following distribution of severity: completely asymptomatic–G 18%, M 21%, Y 20%; mild reaction not exceeding nausea–G 18%, M 18%, Y 20%; and marked reaction associated with vomiting–G 64%, M 61%, Y 60%. This close conformity between therapy and accident data is unexpected, because the Y-12 group received distinctly higher doses. An explanation probably must be sought in two factors: First, because of spontaneous tendency toward nausea, advanced cancer patients may react at lower doses somewhat more vehemently than healthy persons and, second, available data suggests that, within the several-hundred-roentgen range, severity of the initial reaction is not enhanced significantly as the dose exceeds the 300 r level.[6]

Despite similarity in distribution of severity, the patients in the present series and those of the Y-12 group apparently differed in degree of disability. In cancer patients, reactions accompanied by vomiting consistently induced such a marked reduction of physical and mental faculties as to seriously *compromise their performance of difficult or strenuous* tasks. In sharp contrast, of the three persons who vomited in the Y-12 group, two remained in relatively good general condition–even at the height of their reaction–although "mild weakness and over-all ill feeling" existed. Only one man experienced disability comparable to that seen in cancer patients–in this instance, however, disability probably resulted from a reaction that was psychogenic rather than truly physical.[10]

Obviously, caution must be exercised before definite conclusions can be drawn about the extent of disability incurred by healthy persons and by cancer patients, because the sets of data are too small and the significance for civil defense is too critical. Nevertheless, the following points require consideration: As mentioned above, patients with advanced cancer are likely to react somewhat more vehemently; furthermore, since the systemic disturbance represents an additional burden that must be borne by the organism already weakened from preradiation disease, a higher degree of disability is liable to ensue. Thus, with respect to civil defense applicability, observations on cancer patients are probably too pessimistic. Findings in the Y-12 group, on the other hand, are certainly too optimistic because these persons received medical care immediately after the accident and, shortly after onset of nausea, they received antiemetic medication with injections of prochlorperazine dimaleate.[9] It is difficult to decide whether marked disability failed to develop because of therapy or because, by chance, the persons involved possessed relatively low susceptibility. These possibilities must be considered seriously because other accident data closely agree with findings on cancer patients. The case reports of Hempelmann and co-workers[2b] contain several striking examples of the initial reaction which clearly demonstrate that some persons enter a phase of marked weakness or even of complete prostration; disability is most conspicuous during an interval extending from 2 through 10 hours after the accident.

The preceding analysis may be *summarized* briefly as follows: with regard to all aspects–distribution of severity, time course, and extent of disability–there is no difference between the initial reaction in cancer patients and that in healthy persons; however, induction of corresponding degrees of impairment requires lower doses for the first than for the second group.

Other Findings.—Other manifestations were surprisingly inconspicuous and equivocal among the cancer patients in the present series. At the height of the reaction—between the fifth and the eighth hour after exposure—five patients showed a slight elevation of temperature, a trivial acceleration in the rate of pulse and respiration, and a barely perceptible drop in blood pressure. Despite their failure to occur in the remaining six patients, these changes might represent true components of the initial reaction, because similar effects were observed in persons exposed to much higher doses during nuclear accidents.[26]

Report of Cases

To illustrate the points discussed thus far and to demonstrate the various types and degrees of clinical picture, the following three case histories were selected according to a stepwise increase in severity of the initial reaction. No significance should be attached to the fact that the preradiation disease involved abdominal structures in the two patients with the more pronounced forms of reaction, because similar clinical pictures were displayed by other susceptible patients who did not have such an involvement.

Case 3.—Throughout one year prior to admission a 61-year-old woman had suffered from recurrent pleural effusions of unknown origin, necessitating two thoracenteses. During the last few months of that period, she experienced a 25-lb (11.4-kg.) weight loss, shortness of breath with "fluttering" of heart, and enlargement of lymph nodes—particularly conspicuous in both supraclavicular and axillary regions. After admission, biopsy of a scalene lymph node revealed malignant lymphoma—Hodgkin's granuloma.

During the preexposure observation period, the patient was found to be in fair physical condition; throughout most of the daytime she walked about the ward and performed light work. Her morale was good; she liked to converse with patients, nurses, and physicians alike, and she displayed a positive attitude toward both her disease and her new environment. On Aug. 29, 1957, she had breakfast as usual about 8 a. m. Later that morning, total-body radiation (150 r) was administered as follows: first half-dose, 11:08 a. m. to 11:25; repositioning, 11:25 to 11:30, and second half-dose, 11:30 to 11:47 a. m. Completely unaffected by the radiation procedure, the patient resumed her usual activities soon after return to the ward; however, she expressed some resentment about the frequent close examinations. Her temperature, pulse, respiratory rate, and blood pressure showed normal values. At 12:30 p. m. she ate lunch with fair appetite. Around 1:30 p. m.—two and one-half hours after the start of exposure—a spell of malaise erupted suddenly; fatigue, headache, and anorexia appeared as the chief complaints, over which were superimposed brief episodes of nausea associated with regurgitations causing "sour" taste but no frank emesis. After one hour this wave of discomfort largely subsided and was followed by resumption of usual activities; however, listlessness and somewhat subdued behavior persisted. Although the 3:30 examination revealed a small rise in temperature associated with trivial fall of both blood pressure and pulse rate, the patient expressed no complaints. This practically asymptomatic state was interrupted by a second wave of apathy, anorexia, and nausea arising around 5:30—six and one-half hours after exposure. The period of discomfort lasted about two hours; thereafter, the patient returned to a completely asymptomatic state. During the following days, a few periods of poor appetite were the only complaints that conceivably might have been caused by the radiation treatment.

Comment.—The initial reaction of this patient stands out as two waves of mild indisposition, with no appreciable impairment of mental and physical capabilities.

Case 10.—Several months prior to hospitalization a 25-year-old man progressively experienced general weakness, exertional dyspnea, epigastric as well as substernal pain, and loss of body weight. On admission the most prominent findings were generalized adenopathy and a marked reduction of both capacity and distensibility of the stomach, which displayed large gastric rugae. Biopsy of the right lacrimal gland revealed infiltrations of small lymphocytes consistent with the diagnosis of lymphosarcoma.

During the preexposure observation period the patient complained of weakness, nasal congestion, and night sweats; however, he was able to walk and to participate in some activities. On Nov. 5, 1957, the patient had his usual breakfast around 8 a. m., and received total-body radiation (200 r) between 9:30 and 10 a. m. He then walked about the ward and conversed with other patients. This period of obviously unimpaired condition suddenly terminated at noon—two and one-half hours after the start of radiation—with the abrupt onset of marked anorexia and severe nausea, swiftly followed by a bout of vomiting. Lunch could not be eaten. Although vomiting failed to recur, anorexia and nausea persisted unabated until 4 p. m. and then gradually subsided. During the intense phase of discomfort—extending from two and one-half through six hours after exposure—the patient appeared apathetic, weak, and too listless to walk. At the height of the reaction his temperature rose to

100 F (37.8 C) while his pulse rate, respiratory rate, and blood pressure remained practically unchanged. Late in the afternoon, improvement became clearly evident; some supper was eaten at 5 p. m., and thereafter ambulation could be resumed, although slight listlessness still persisted. On the next morning the patient appeared asymptomatic and ate his entire breakfast with good appetite.

Comment.—The initial reaction of this patient caused a moderate impairment of mental and physical fitness which was clearly evident throughout a five-hour period starting at two and one-half hours after irradiation. During that interval, his ability to execute strenuous tasks would have been doubtful, at best.

CASE 5.—About three months prior to admission, a 69-year-old man noticed development of a tumor in the epigastrium. Growth of the mass was paralleled by increasing polydipsia, polyphagia, polyuria, and weight loss. Examination on admission revealed lymphadenopathy, particularly prominent in the left parietal and left axillary regions. Exploratory laparotomy and biopsy disclosed that the large abdominal mass was a malignant giant-follicle lymphoma.

During the preexposure observation period the patient's physical condition was fair; he liked to roam about the ward and to assist in little tasks. Displaying a bright and cheerful attitude, he easily and swiftly established friendly relations with other patients as well as with hospital personnel. On April 9, 1957, he had his usual breakfast around 8 a. m. Total-body radiation (150 r) was started at noon and was completed by 12:40 p. m. After return to the ward, the patient displayed his normal cheerful attitude in explaining to others the procedure through which he had just passed. Subsequent to the 1 p. m. lunch, eaten with perfect appetite, he slept for one hour, as was his custom. This completely asymptomatic period ended sharply at 3:20 p. m. when vomiting suddenly started. Concomitant with the onset of repeated emeses—producing large amounts of undigested food and watery fluid—increasing lethargy developed. Muscle strength, particularly in the lower extremities, was distinctly reduced, and the gait appeared unsteady and ataxic. The distress reached a climax between 5 and 6 p. m. At that time, the patient became prostrated and mentally depressed; his temperature rose from 98 to 101.2 F (36.7 to 38.5 C) while pulse, respiratory rate, and blood pressure remained unchanged; attempts at eating supper were answered immediately by such severe bouts of vomiting as to necessitate oral administration of 25 mg. of chlorpromazine hydrochloride. The period of intense disability lasted for about five hours. Around 8:30 p. m. marked improvement had already made its appearance, as indicated by resumption of ambulation, consumption of a small meal consisting of corn chips and oranges, and the drinking of some water. On the next morning, the patient appeared asymptomatic; muscle strength had completely returned, and breakfast was eaten with normal appetite. During the following days, no complaints related to the radiation treatment were expressed; however, some waves of anorexia, extending into the fourth postradiation day, perhaps must be regarded as the last remnants of the initial reaction.

Comment.—The initial reaction of the patient caused a severe transitory depression of both mental and physical capabilities; the period of disability began three and one-quarter hours after start of irradiation and lasted for about five hours. During that interval, diligent execution of any task would have been impossible.

Comment

The subsequent discussion of the initial reaction will center around two aspects—namely, first, its potential significance in the atomic age and, second, its therapeutic management.

Civil Defense Aspects.—When medical assistance is readily available, as it is in both radiotherapy and reactor accidents involving small numbers of persons, the initial reaction represents a bothersome but insignificant side-effect that, due to its short duration, rarely poses serious problems. This harmless disorder may assume quite a different role, however, when certain civil defense situations are analyzed.[8] Obviously, nuclear disasters can assume such dimensions that exposed persons, in order to reach medical facilities, may have to endure several hours of driving or walking through streets congested by vehicles and panic-stricken people. Thus, while on their way, they become affected by the disturbance and thereby suffer reduction of fitness at a time when ultimate physical and mental efforts are necessary for survival. In a small group of hypersensitive persons, reactions probably will attain such severity as to imperil escape from the disaster area without aid. Therefore, the disturbance must be taken into account by authorities designing evacuation plans and other emergency measures which require the active participation of exposed populations.

The several-hour delay between exposure and arrival at medical facilities also has another implication demanding the physician's attention: on admission, exposed persons may already display initial reactions. Radiation-induced dizziness, nausea, and vomiting—when occurring in patients with mechanical or thermal lesions, particularly of head and abdomen—can easily be mistaken for sequelae of these other injuries. Thus, unrecognized, the initial reaction may jeopardize proper diagnosis, prognosis, and classification of casualties.[8]

Therapy.—Owing to its unsolved pathogenesis, the reaction can be neither prevented nor treated with specific remedies. Nevertheless, clinical experience has firmly established several principles of management which, when properly applied, enable alleviation or even suppression of overt manifestations in many instances. Among these principles, psychological reassurance plays a leading role because, similar to motion sickness, the initial reaction frequently is aggravated by apprehension or introspection. Such reassurance becomes especially important in civil defense situations in which uncertainty and fear, triggered by the onset of nausea and vomiting, may grow so powerful as to induce an outbreak of mass hysteria in an uninformed exposed population. Education must center around two characteristic peculiarities of the initial reaction—namely, first, its brief transient course and, second, its relative insignificance as an indicator of received doses; in a wide dose range, the severity of clinical manifestations is determined much more by individual susceptibility than by the amount of radiation.[6] Radiotherapy experience demonstrates that proper psychological preparation frequently suffices for controlling the distress.

When these measures prove insufficient, however, additional steps must be taken. Among the drugs, probably all sedatives are beneficial; by contributing to the restoration of equanimity they support psychological measures, and by depressing the excitability of autonomic centers they raise the threshold for nausea and vomiting. Selection of type and dose of medicament is determined by the given situation; often, the drug of choice will be one that acts almost exclusively on the medullary autonomic centers but does not affect cortical functions. Since barbiturates possess certain deficiencies in this regard, they have been increasingly replaced by more effective chemicals developed during recent years—e. g., meclizine hydrochloride, prochlorperazine maleate, and chlorpromazine hydrochloride. According to clinical experience, the combination of psychological measures and drug medication leads to a satisfactory alleviation of the initial reaction in practically all cases. Only the occasional hypersensitive patient will develop disturbances of such a degree as to necessitate parenteral administration of fluid, glucose, and protein.

Summary

Early clinical manifestations displayed by 11 cancer patients after whole-body roentgen radiation in one single large dose are compared with previous reports of "radiation sickness" and with acute sequelae observed in persons exposed in nuclear accidents. From this comparison, the typical initial reaction to penetrating radiation in the several-hundred-roentgen range appears to be as follows: signs and symptoms—essentially in the form of fatigue, nausea, and vomiting—begin to develop within two to four hours after exposure; they reach a climax somewhere between five and eight hours afterward; and they completely subside on the second or third day. During the intense phase of the disturbance, extending from approximately 4 to 10 hours after exposure, about 60% of irradiated persons experience various degrees of disability.

Despite its transitory nature, the reaction may present a major medical problem in civil defense situations because of coincidence and, thereby, interference with evacuation plans and first-aid procedures. Therefore, the early sequelae of exposure to penetrating radiation require the attention of all physicians who may have to manage such emergencies.

CLINICAL NOTES

NEW THYROIDECTOMY RETRACTOR

Lyman C. Blair, M.D., Houston, Texas

In performing total thyroidectomy or lobectomy for suspected carcinoma of the thyroid, it is necessary to retract the thyroid tissue. Current methods for doing this include the use of the Lahey goiter vulsellum forceps and the placement of silk or nylon sutures through the thyroid. The latter method seems to be the most common among the practitioners in my community at this time.

Both of these methods involve cutting and massaging (more bluntly, squeezing) of the thyroid tissue, while its circulation remains continuous with the general body circulation. Since both cutting and squeezing are involved, it would seem that there remains a possibility that cancer-cell emboli may be disseminated. At any rate, distant metastases may later become apparent, and the part played by the thyroidectomy in causing them may be impossible to assess.

I have devised a new type of retractor for thyroidectomy and removal of thyroid nodules, which I believe should save at least some wear and tear on surgeons' consciences (see fig. 1). Because of the slow growth of many thyroid cancers, with late metastases, it will require many years for assurance that dissemination can be prevented by the use of this retractor; hence, by the time it is really proved, it is hoped that systemically acting cancericidal drugs will have rendered it obsolete.

It consists of three hemispherical suction cups and appurtenances necessary to make them useful for the purpose intended. They are each about ⅝ in. in diameter and are arranged in a straight line; each is provided with a metal drain (or actuating) line, and these converge and join to a nipple. The nipple is to be attached to the suction apparatus available in all operating rooms, by means of the usual rubber hose. There is a finger ring or handle attached for application of traction after the device is in use. A metal strut helps maintain the cups in the proper position relative to each other.

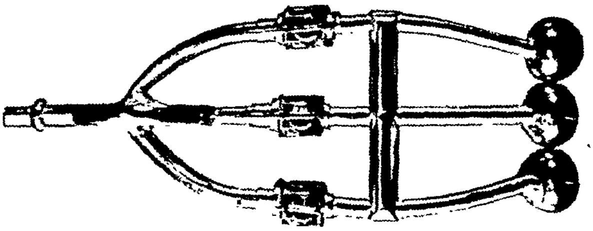

Fig. 1.—Chrome-plated brass retractor, with "three-way" valves.

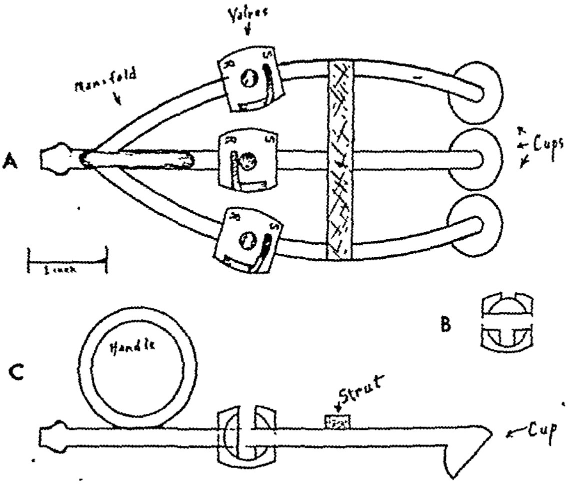

Fig. 2.—Suction thyroid retractor. A, plan view. B, valve in "suction" position. *C,* sagittal section, with valve in "release."

"Three-way" valves are placed in each individual cup's suction line (fig. 2). This is to provide for restoration of the pressure within the cup to atmospheric pressure, whenever it may become necessary to reposition these. If such valves were not used, the force necessary to release a cup from the tissue would be traumatic.

Due to the wide variations in the size and shape of thyroid glands, I deem it necessary to have at least three individual cups, with individual control. One, two, or three cups may thus be used at any given time, without the loss of effectiveness and the unnecessary noise which would result if one or more lines remained open to the atmosphere.

Although some compression of tissue will still result from the use of this device, there is no cutting; and, if the compression results in the freeing of cancer-cell emboli, there is a fair likelihood that they may be sucked into the retractor itself, where they will do no harm.

COUNCIL ON DRUGS

Report to the Council

The Council has authorized publication of the following report.

H. D. Kautz, M.D., *Secretary.*

CURRENT STATUS OF THERAPY IN MICROBIAL FOOD POISONING

G. M. Dack, M.D., Chicago

Microbial food poisoning is frequently associated with acute illness of short duration. When the physician arrives in response to a telephone call, convalescence may be well under way. Because of the transient nature of the illnesses and the tendency for rapid convalescence, the general practitioner usually has had little opportunity to study them.

Microbial food poisoning falls into two principal categories. The first is one in which the causative microbes grow in a food and elaborate an exotoxin, for example, botulism and staphylococcus food poisoning. The second is one in which the causative living organisms multiply in a food product, and large numbers are required to produce infection. Examples of this group are Salmonella infections and food poisoning from certain streptococci, and from Bacillus cereus and Clostridium perfringens. Many of the viral and infectious agents may be disseminated in foods, but only those associated with gastrointestinal upsets are considered under the loose terminology "food poisoning."

In order for the physician to prescribe treatment, it is important that he have some idea as to the type of agent causing the illness. Implicated food may suggest the causative agent. However, before the implicated food has been determined, the symptoms, together with the period of their onset after a specific meal, are useful in directing attention to the causative agents. As an aid in finding the causative agent, the table gives the essential features of the various types of microbial food poisoning.

Botulism

Outbreaks of botulism are rare, and many types of illness have been confused with this disease, e. g., poisoning from pesticides such as sodium fluoride, methyl chloride poisoning, as well as cases of septic meningitis. In the United States the majority of outbreaks of botulism are related to the consumption of inadequately processed home-canned vegetables of low-acid content such as string beans, beets, and other vegetables. Usually there is evidence of spoilage by off-odors or flavors of such foods which are not a particularly good medium for the growth of Clostridium botulinum. Growth of the common types A and B of Cl. botulinum in meat products is accompanied by gross evidence of putrefaction, and for that reason such products are usually not eaten. In some homes, spoiled canned foods are given to chickens which develop limberneck and die. Such illness in poultry has sometimes provided the physician with useful clues leading to the diagnosis of botulism.

Five types of Cl. botulinum, labeled A, B, C, D, and E, are recognized. The types have certain biochemical reactions which differ, but their toxins cause the same kind of symptoms in man.

The mode of action of botulinum toxin in the body is not fully understood. However, the toxin appears to interfere with the production of acetylcholine, since a muscle in a physiological preparation poisoned by botulinum toxin will contract when acetylcholine is injected intra-arterially. A muscle in a similar preparation poisoned by curare does not react when treated with acetylcholine. Small amounts of either type A or type B toxin decrease the synthesis of acetylcholine in both in vivo and in vitro experiments. Some investigators have suggested an interaction of toxin, with the fine unmyelinated nerve fibers entering the end-plate region, thus causing a block of the nerve impulses. When the mechanism of the mode of action of botulinum toxin is discovered, perhaps a better treatment of the disease will be forthcoming. Until such a time, the only specific treatment is administration of antitoxin of the type causing the illness.

Each of the toxins is neutralized by a specific antitoxin. The most common types affecting man are A and B; type E less commonly, and types C and D have been rarely reported. Type E has been associated with fish or roe which has undergone spoilage. The treatment of botulism is, at best, unsatisfactory, and the mortality in the United States

---

Director, Food Research Institute and Professor of Microbiology, University of Chicago.

is about 65%. If a physician finds patients with symptoms suggesting botulism, it is advisable to determine whether low-acid, home-canned foods have been consumed from one to three days previously. When symptoms are well advanced, antitoxin therapy is of little value. However, antitoxin will prevent damage by the toxin which is not already fixed in the central nervous system. At least 50,000 units of each of type A and B botulinum antitoxin should be given intramuscularly after the patient has been tested for hypersensitivity, and, if necessary, has been desensitized. At least 10,000 units diluted in 5 or 10% dextrose injection may be administered intravenously every 18 to 24 hours.

Enemas are recommended for washing out the colon to eliminate toxin which might be retained because of constipation. The physician should attempt to prevent aspiration pneumonia. Fluids taken orally are avoided in pharyngeal weakness or paralysis. The secretions in the mouth and throat should be aspirated continuously with a soft rubber tube and an aspirating machine. Fluid and electrolyte balance are maintained with dextrose and sodium chloride injection given intravenously. Oxygen is administered for cyanosis, and artificial respiration may be required. There is no agreement among clinicians regarding the value of respirators in the treatment of botulism.

In the treatment of shock, whole blood and plasma should be given. Antibiotics and sulfonamides should be administered in appropriate amounts to prevent secondary infections. The patient should be kept in quiet, restful surroundings and encouraged to avoid unnecessary muscular exertion.

Patients who have eaten generously of the incriminated food develop symptoms of botulism early, and antitoxin does not repair damage already done to the tissues. Frequently, persons who have eaten less of the incriminated food may be treated with antitoxin before symptoms appear, and there is an excellent opportunity for them to benefit prophylactically from the administration of antitoxin. Antitoxin should always be administered, since it will unite with uncombined toxin and prevent its damaging the tissues.

Staphylococcic Food Poisoning

Staphylococcic food poisoning is the most common type encountered in the United States. Since staphylococci are ubiquitous, it is impossible to protect foods from them. Enterotoxin-producing strains causing acne and other pyogenic infections may be imparted to food through handling. Many apparently normal food handlers may carry food poisoning strains in their nose and throat. Staphylococci can withstand high concentrations of sugar and salt, and for that reason certain foods may serve as a selective medium for them. In order for an outbreak to occur, a food poisoning strain of staphylococcus is required, a food in which it will grow, plus time and correct temperature. With a generous seeding of the right type of staphylococcus, five to seven hours at a warm temperature is sufficient for enterotoxin to develop. The site of action of enterotoxin in the body has not been established. Enterotoxin may be produced in vivo when the organism is confined to pyogenic lesions in the body or in the intestinal tract, where the normal intestinal flora is abolished by the action of large doses of broad-spectrum antibiotics.

Characteristics of Food Poisoning Caused by Bacteria or Their Products

Disease	Specific Agent	Intoxication	Infection	Symptoms	Onset of Symptoms after Eating	Foods Usually Involved
Botulism	Toxin of Clostridium botulinum	+	—	Difficulty in swallowing, double vision (diplopia), difficulty in speech (aphonia), difficulty in respiration, followed by death from paralysis of muscles of respiration	2 hr.-8 days; av., 1-2 days	Home-canned, low-acid products (toxin in food destroyed by boiling)
Staphylococcic food poisoning	Enterotoxin of staphylococci	+	—	Nausea, vomiting, diarrhea, acute prostration, abdominal cramps	1-6 hr.; av., 2½-3 hr.	Ham, cream-filled bakery goods, cheddar cheese, dry skim milk, poultry, potato salad (enterotoxin in food not destroyed by boiling)
Salmonella infection	About 600 serotypes of Salmonella, 40 of which are more common	—	+	Abdominal pain, diarrhea, chills, fever, frequent vomiting, prostration	7-72 hr.	Inadequately cooked egg products, poultry, or other foods
Streptococcic food poisoning	Enterococci	—	+	Nausea, sometimes vomiting, colicky pains, diarrhea	2-18 hr.; av., 8-12 hr.	Inadequately refrigerated foods contaminated with enterococci
Bacillus cereus food poisoning	Bacillus cereus	—	+			Starch foods inadequately refrigerated
Clostridium perfringens food poisoning	Clostridium perfringens	—	+			Poultry and meat products cooked and left unrefrigerated at warm temperature for several hours

The short incubation period after a specific meal is characteristic of staphylococcic food poisoning. Especially is this so when a number of people develop similar symptoms after a common meal. The severity of the symptoms depends on the potency of the enterotoxin in the food consumed. When small amounts of enterotoxin were fed to human volunteers, some developed vomiting without diarrhea and others cramps and diarrhea without vomiting. With the smaller amounts, the time of appearance of symptoms after ingestion of enterotoxin was longer, varying from four to six hours. When large amounts of enterotoxin were fed to human volunteers, the time of appearance of symptoms was shortened (45 minutes to 2 hours). Nausea, vomiting, cramps, and diarrhea occurred in the severe cases, and blood was found in the vomitus and stools. Acute prostration was usually present in severe cases, and patients might experience a sharp fall in blood pressure and develop shock. Death, although rare, may follow in debilitated persons or in very young children.

Perphenazine (Trilafon) has been found to prevent vomiting in experimental animals which are later fed enterotoxin. It has not been evaluated in the treatment of staphylococcic food poisoning in man.

Since the vomiting and diarrhea are pronounced in staphylococcic food poisoning, there is no need to administer emetic or purgative drugs. Vomiting and diarrhea are nature's effective method for eliminating unabsorbed enterotoxin. Abdominal pain may be relieved by codeine sulfate (30 to 60 mg.) or morphine sulfate (10 to 15 mg.). The most important therapeutic problem concerns dehydration and shock. Fluid balance should be restored by the intravenous administration of sodium chloride injection with 5% dextrose, 2,000 to 4,000 cc. in 24 hours. Patients adequately treated with fluids given parenterally recover quickly, and the period of convalescence is shortened. Caffeine sodium benzoate (500 mg. parenterally) may be required for severe prostration. Plasma and blood may be necessary therapeutic measures in the management of shock. Food or liquid by mouth is withheld until nausea and vomiting have stopped. Rice, clear broths, and tea may then be taken orally. Subsequently, the diet is enlarged gradually but limited temporarily to bland foods until the illness has subsided. Broad-spectrum antibiotics should not be given in the treatment of staphylococcic food poisoning, since many of the food poisoning strains of staphylococci are resistant to antibiotics. I am familiar with a patient who had a severe case of staphylococcic food poisoning and who was treated with large doses of chlortetracycline (Aureomycin) hydrochloride to which the causative staphylococcus was resistant. The patient developed a relapse of symptoms within 48 hours and died. Staphylococci ingested with incriminated food do not find conditions suitable for multiplication in the intestinal tract, since the normal microbial flora prevents their multiplication. Thus, it is important not to interfere with the normal microbial flora by the administration of broad-spectrum antibiotics.

Salmonella Infections

There are about 600 serotypes of Salmonella micro-organisms. Those concerned with the production of typhoid and paratyphoid fevers are not considered in this discussion. Approximately 40 types cause the majority of illnesses, which are food-borne and which give rise to infection lasting one or two days and commonly referred to as food poisoning. Some of these food poisoning strains invade the blood stream and cause infections lasting many days.

Salmonellae are abundant in nature and are found most commonly in the intestines of poultry and swine. They produce infection in animal species including cold blooded as well as warm blooded animals. They are present on the shell of eggs, and, when eggs are broken commercially, they find their way into frozen whole eggs, yolks, whites, and in dried egg products. These commercial egg products are used in the preparation of many food products including "convenience" foods, some of which are inadequately processed to destroy viable salmonellae.

Some students of enteric microbiology are under the impression that the incidence of salmonellosis is on the increase, as judged by the demand for serotyping of cultures; however, since there is no uniformity of reporting of these cases, there is no evidence to substantiate these impressions. Widespread outbreaks, due to specific unusual strains of Salmonella, have been reported which were thought to be related to food items in national distribution.

The predominant clinical picture is gastroenteritis, mostly mild in character, though a few cases may develop with typhoidal symptoms and fatalities among them. In one large outbreak in a city, there were 1,800 cases, with 11 fatalities due to Salmonella typhimurium. Complications are uncommon but include thrombosis, thrombophlebitis, pyelitis, osteomyelitis, dehydration and toxemia, arthritis, and, in young children, meningitis. Diarrhea may last for a few hours up to four to six days. Vomiting occurs occasionally.

The number of Salmonella organisms required to cause illness undoubtedly depends upon the age and susceptibility of the individual. Small numbers of organisms fed experimentally to some persons, although producing no illness, have sometimes resulted in a carrier state. From the public health standpoint it is desirable that no viable Salmonella, even in small numbers, be present in foods at the time they are eaten.

The treatment of Salmonella infections is largely symptomatic and is similar to that described for staphylococcic food poisoning. The intestinal tract is freed naturally of large numbers of Salmonella organisms by diarrhea, and only symptomatic treatment is needed.

Stool cultures should be made to determine whether Salmonella organisms are the cause of the illness. If symptoms of fever and toxemia are present for more than a day or if complications develop, a search should be made in the laboratory by sensitivity tests for an antibiotic to which the Salmonella strain is sensitive. No one antibiotic has been discovered to which all Salmonella strains are sensitive. In one large outbreak, oxytetracycline (Terramycin) hydrochloride, chlortetracycline hydrochloride and chloramphenicol (Chloromycetin) were used in treatment, with no appreciable benefit. In other instances Salmonella serotypes have responded to these and other antibiotics.

An antibiotic which is effective in vitro against a specific Salmonella strain should be administered to the patient in adequate dosage, with due precautions taken with reference to undesirable side-effects from the drug being administered.

Streptococcic Food Poisoning

Food poisoning caused by the alpha hemolytic streptococcus presents identical symptoms with that caused by B. cereus and Cl. perfringens, namely cramps and diarrhea, with only occasional vomiting, coming on usually 11 to 12 hours after eating a food item containing many millions of these organisms per gram. The incubation period may vary from 2 to 18 hours. There is usually no fever or leukocytosis, and the symptoms subside in the course of a few hours. No specific treatment is indicated, since the organisms do not establish themselves as a predominant flora in the intestinal tract. The mode of action of these agents in the production of illness has not been established.

When the streptococcus has been classified in several outbreaks, it has been found to be an enterococcus. This type of food poisoning has been studied in human volunteers, and, in many instances, illness has not resulted when large numbers of the enterococci have been fed. In other instances, illness has followed when freshly isolated cultures have been fed. More work is necessary to elucidate the mechanism by which illness results. Outbreaks have been associated with meat items and turkey dressing which have stood at warm temperatures for a number of hours, allowing profuse growth of enterococci.

Bacillus Cereus Food Poisoning

Outbreaks of food poisoning caused by B. cereus have been described in Norway. One large outbreak was traced to a ready-mix, vanilla pudding purchased from a grocery store, which was cooked and allowed to stand at a warm temperature until the following day when it was served. B. cereus is a spore-forming organism commonly found in the soil and therefore a natural contaminant of cereal products. The spores may not be destroyed in cooking and hence may germinate and grow rapidly in a food if conditions of moisture, time, and temperature are right. Illnesses have been produced in volunteers, but again more information is needed to determine the mechanism causing B. cereus food poisoning. No specific treatment is indicated since the symptoms are mild and of short duration. The diarrhea removes the organisms from the intestinal tract, and B. cereus fails to establish itself in the intestine.

Clostridium Perfringens Food Poisoning

Cl. perfringens has been found to cause many outbreaks of food poisoning in Great Britain. There is no doubt that many outbreaks occur in the United States, but seldom do laboratories examining implicated foods search for Cl. perfringens. The strains found to cause food poisoning produce extremely heat-resistant spores. Subcultures of strains from foods do not yield spores with the heat resistance of the original contaminants. The natural habitat of these strains is the intestinal tract of animals. Illnesses have been produced experimentally in human volunteers, particularly when the strain has been grown in a food which was involved in the outbreak. Negative tests among humans have occurred when old strains from outbreaks have been grown in common culture medium. The mechanism of the illness caused by Cl. perfringens is not understood. Outbreaks have commonly followed eating of meat products which have been cooked and allowed to stand at warm temperatures. In such instances the spores of Cl. perfringens contaminating the meat have not been destroyed but germinate and grow when the product is not refrigerated. No treatment is indicated for food poisoning from Cl. perfringens, since the symptoms are mild and the organism does not predominate in the intestine after the acute illness.

EYE-SIGNS IN HYPOTHYROIDISM.—Among the many signs of hypothyroidism, puffiness of the eye-lids is a familiar feature of the facial appearance, but watering of the eyes is not usually reported as a prominent symptom. Recently we have seen five patients who presented to an oculist complaining of watering of the eyes in whom there was found evidence of hypothyroidism and whose symptoms were relieved by the administration of thyroid extract. In two other cases which presented to physicians, one of primary hypothyroidism and the other of hypopituitarism, watering of the eyes and puffiness of the lids were prominent symptoms which responded to treatment with thyroid extract.—W. H. Smith, K. G. Howsam, and J. J. Billings, Epiphora, *British Journal of Ophthalmology,* October, 1959.

Supererogation

A popular dictionary defines supererogate as "to do more than is required by duty or obligation," and at least one physician thinks it might make an excellent rule for doctors, when listening to patients.

Writing in the November issue of the *Medical Annals of the District of Columbia*, Dr. I. P. Frohman says, "The greatest complaint of patients is 'My doctor doesn't take the time to listen to me.'" And Dr. Frohman should know. He is the author of two recent and popular articles in a lay magazine which have resulted in his receiving hundreds of letters from concerned patients. He writes:

"These people, who represent a cross section of the United States, feel frustrated and restrained. They want to unburden, to talk to their doctors, but time does not permit this . . .

"Do we have a scientific computer to take the place of patient-to-doctor, doctor-to-patient talking and listening? And would you buy one if we had? I believe as did Osler and other eminent physicians through the ages that there will never be a test, a machine, or a method to take the place of just sitting and listening to our patients.

"We speak glibly of getting an accurate history from the patient . . . yet when the patient digresses a bit, he is gently, and sometimes not so gently, put back on the original trend of thought . . .

"Here then is the place for supererogation for the physician. Perhaps a small sign facing us squarely in the eye—LISTEN, DOCTOR—might be the solution for us and our patients."

Medics for the Multitude

Doctors Volunteer for Olympic Duty As Squaw Valley's Population Booms

Although more than 1,000 athletes are currently performing on acres of ice and snow at the VIII Olympic Winter Games in Squaw Valley, Calif., chances are that the spectators and not the participants will need the medical attention, and flu instead of fractures will lead the list of complaints.

Whatever the problems and wherever they are happening—on the slopes, rinks, jumps, or trails—Squaw Valley is ready for them, with all the manpower, facilities, and equipment likely to be needed. But there is no magic in this appearance of a topnotch medical service program. It took 14 months of planning by Dr. William B. Stiles, who is a professor of public health at the University of California at Berkeley when he isn't organizing Olympic health and medical services.

His preparations have been based on an estimated Valley population of 40,000 during the 10-day period of the games, but participants and other personnel began arriving Feb. 1, so it was then that the health and medical service really began operations. People are, of course, the key to Dr. Stiles's effort. He has 80 physicians on a billet list, and another 20 in reserve. There is also a pool of 60 nurses, although no more than 30 are expected to be needed at any one time. In addition, there are ambulance drivers, x-ray and laboratory technicians, physiotherapists, and even a dentist. Five persons—the chief physician, the assistant medical director, the chief nurse, a laboratory technician, and an x-ray technician—will be on 24-hour call.

All these people are working without pay, but they are being furnished with board and room. All are volunteers, although no

Skis swish through powder snow and skates carve the glittering ice, as thousands congregate for the VIII Olympic Winter Games. For the story of medicine's part in this sports spectacle, see the story above.

public plea was made. Somehow, the word got around, and the takers outnumbered the offers. Most of the volunteers are Californians, although some doctors from other states will take part. Special legislation will allow the out-of-staters to practice during the Olympic period. Both Nevada and California medical associations have approved the project.

Most spectacular of the services now in operation is the 10-man squad of skiing physicians. Spotted throughout the area, the doctors are instantly available for aid to disabled skiers and can be summoned either by radio or an emergency phone network.

The alacrity with which professional help volunteered leads Dr. Stiles to think that "They are all looking forward to their duties with the idea they'll get some fun out of it, but they know they're in for some hard work too." Duty periods have been scheduled to allow each volunteer some free time.

Mainstay of the facilities provided for the Squaw Valley medical service is a 28-bed, licensed hospital complete with an operating room capable of handling major surgery, although most patients needing surgical care will probably be evacuated to the nearby Tahoe Forest or Reno hospitals. Two Quonset-hut wards are connected to the main building by covered walkways. Food service is provided from a nearby kitchen. There are nine medical aid stations spread throughout the area. In addition, there are three training or physiotherapy rooms, a fleet of ambulances, several station wagons and over-snow vehicles, and offices for health personnel.

Ski patrols with years of experience in caring for injured sportsmen have pretty well standardized rescue techniques. Squaw Valley patrols will use an aluminum shell-type sled to remove the patient to the nearest aid station or ambulance point. Arrangements have also been made with the Stead Air Force Base at Reno, Nev., to airlift patients to a hospital, if need be.

To be genuinely useful, facilities demand equipment, and that problem has been met ingeniously too. The Department of Defense has loaned many items, and others have been offered by private firms. Pharmaceutical supply houses are providing medical supplies, with the understanding that unused items may be returned.

A Shot in Time

Heeding warnings of the possible outbreak of Asian flu again this year, Dr. Stiles began an immunization program two months ago, in an attempt to keep respiratory problems from wreaking havoc with the Games.

The possibility of such an occurrence was strongly impressed on him a year ago when flu cases outnumbered all others in a pilot run held during the trials for the American and Canadian teams.

Realizing that some of the greatest problems at the Games might result from a breakdown of sanitation measures, Dr. Stiles has assigned the task of overseeing them to a four-man squad headed by a professional health officer. The four are keeping a constant check on the area's water, milk, food storage and preparation, vermin control, and sewage disposal.

Medical care is available in the Valley for all contestants, officials, employees, and volunteers. Emergency care for spectators is furnished, but spectators needing continuing treatment are being referred to outside physicians.

Although he is modest about it, Dr. Stiles has a background well suited to the task at hand. As a former regional director for the Federal Civil Defense Administration, he is used to planning the medical care of large numbers of persons. And in 1952, he directed the health and medical planning for another major event held in California—the Boy Scout Jamboree.

Welcome Those Teen-agers But Monitor Their Actions

Magazines and Sunday supplements have painted many a glowing picture of adolescent volunteers at work brightening the days of local hospital patients, but the American Hospital Association warned last month that such blessings require adequate restriction.

An AHA-approved publication, entitled "The Teenage Volunteer in the Hospital," notes that such a program should be considered "primarily as an educational procedure, and part of the hospital's total community education program." Such areas as the maternity floor, the operating and emergency rooms, and the medical records section should be off limits to such teen-agers, the booklet says.

The publication notes, "No teenager should be allowed to have prolonged or sustained patient contact or [to] fill direct requests from patients. Neither should they be assigned to hospital-directed patient service outside the confines of the institution nor to any task which involves the handling of money."

The publication suggests that, ideally, such teen-age helpers should be between 16 and 18 years of age but that the age may be lowered to 14, contingent on the duties to be assigned and the supervision available.

What do the children get in return for their labors? "An opportunity to learn the moral satisfaction of constructive service to a community institution . . . and a sense of community responsibility."

Chemical Tests versus The Drinking Driver

"I had only two beers. Naturally I acted a little upset when the police told me I was being arrested." The speaker, a neatly dressed, mild-mannered man, was making his first appearance in court on a charge of driving under the influence of intoxicants. Arresting officers testified his automobile weaved, his breath was alcoholic, and he staggered and was belligerent.

His case is similar to thousands which judges and juries must decide every year on the basis of conflicting testimony.

How to remove much of the uncertainty is discussed in detail in a newly published A. M. A. manual, "Chemical Tests for Intoxication." Fourteen authorities shared in the writing of the 103 pages, bringing under a single cover material previously available only if gleaned from varied sources. The publication was prepared by the A. M. A. Committee on Medicolegal Problems and 1,500 copies have been printed for distribution to physicians without charge and to other interested persons for one dollar (see Medicine at Work, THE JOURNAL, July 19, 1958).

Traffic accidents in this nation kill 40,000 persons every year and injure many more. Dr. Herman A. Heise of Milwaukee, Committee Chairman, cites four independent surveys which show that one-third of the accidents are caused by a driver or pedestrian under the influence of alcohol.

Dr. Heise says intoxication would appear to be one of the easiest diagnoses for a physician to make, yet it is one of the hardest to substantiate in court. How, he asks, can the doctor prove the accused was not suffering from a traumatic brain injury, diabetes, multiple sclerosis, or any of a hundred other ailments with symptoms resembling those of intoxication? A wide disparity between popular beliefs about alcohol and scientific observations is noted by other authors who urge that evidence based only on opinion be mistrusted.

The Arizona View

Standards for judging drinking by drivers vary widely throughout the United States. There is one which has been selected as a model by the A. M. A. and the National Safety Council. It is the definition of the Arizona Supreme Court:

"The expression 'under the influence of intoxicating liquor' covers not only all the well known and easily recognized conditions and degrees of intoxication but any abnormal mental and physical condition which is the result of indulging in any degree in intoxicating liquors, and which tends to deprive him of that clearness of intellect and control of himself which he would otherwise possess.

"If the ability of the driver of an automobile has been lessened in the slightest degree by the use of intoxicating liquors, then the driver is deemed to be under the influence of intoxicating liquor. The mere fact that the driver has taken a drink does not place him under the ban of the statute unless such drink has some influence upon him, lessening in some degree his ability to handle said automobile."

Chemical tests for intoxication have been in use over 50 years, and more than 200 analytic methods of testing for the presence of alcohol have been developed. The manual provides instructions on conducting some common tests through sampling blood, breath, or urine. The reader is cautioned, however, that rapid adoption of testing methods could lead to mistakes which upset prosecutions and impair public confidence in the tests themselves.

Ideally, the phrase "under the influence of intoxicants" would mean the same in all states, perhaps all nations. How far the ideal is from reality is shown by legal writers, who review legislation and court decisions in various states.

The man who claims to have consumed only two beers (but actually lost count) might be acquitted in California, where courts have held that the prosecution must prove alcohol has reduced the defendant's driving ability below that of the poorest driver on the road.

Tests May Be Misused

This same defendant in Arizona probably would be convicted. The Arizona State Supreme Court definition has been praised as a model for other states to follow by both the A. M. A. and the National Safety Council. It says, in substance, that a driver is guilty if alcohol has lessened his driving ability in the slightest degree, although merely taking a drink does not place him under the ban of the statute.

As early as 1939 the A. M. A. House of Delegates advocated a threefold division of blood tests of defendants: (1) Any driver whose blood showed a concentration of 0.15% of alcohol or more would be guilty. (2) Any driver whose blood test result showed 0.05% or less would be innocent. (3) A test result between these limits would be weighed along with other evidence in deciding guilt or innocence.

Some European countries have adopted the policy of convicting all drivers whose blood contains 0.05% or more. This could include some persons who actually had no more than two beers.

In the United States, on the other hand, judges and prosecutors frequently take the position that no person with less than 0.15% of alcohol in his blood should be prosecuted. One of the authors calls this "a perversion of the intent of the testing program," offering a refuge to many drivers who are arrested and actually are intoxicated.

The A. M. A. in the Capital

The Washington Team Serves Both Medicine and the Nation

The United States government now is spending about 4% of its budget on medical-health activities. In the current fiscal year the total is 3.16 billion dollars, not counting another 5 billion dollars paid to disabled persons under aid programs financed entirely or in part by federal funds.

What impact will expenditures of this size have on medical practice? What will be learned from research at the National Institutes of Health, for which 400 million dollars has been appropriated this year? Can private practitioners help the studies there? About 500 bills related to medicine were introduced in Congress last year. What is their status now and what new bills will be introduced this year? Administrative agencies almost daily are required to make decisions pertaining to health problems in the nation. Who will present the thinking of America's doctors?

A physician in Maine or California obviously is unable to keep abreast of affairs in government that are of interest to his profession. The A. M. A., however, tries to perform this service for him, through its officers, committee members and paid staff workers. A vital part of the work is performed by the Association's Washington team, which consists of 23 persons working out of an office at 1523 L St. N. W. The team includes physicians who maintain a liaison with the administrative agencies, attorneys who are familiar with the legislative processes, and journalists who report on Washington events of significance to physicians.

Dr. Roy T. Lester, manager of the Washington office, says it operates strictly as an extension of Association headquarters in Chicago. "We make no policy decisions. Our function is implementation of policy previously established by the A. M. A. policy-making body." Key men in Washington report directly to their division heads in Chicago. Daily contact between the two cities is maintained by teletype, and weekly group conferences are conducted by telephone to keep staff members in both cities fully informed.

Doctors Know Government

Dr. Lester, former medical director of Blue Cross and Blue Shield of Texas, is one of three physicians on the Washington staff, all of whom joined it last year. Dr. Otis L. Anderson, formerly with the U. S. Public Health Service for 30 years, retired as assistant surgeon general. Dr. Eugene V. Jobe was in the U. S. Navy for 30 years, retiring as director of the professional division of the Bureau of Medicine and Surgery.

Drs. Anderson and Jobe have both had lengthy assignments in Washington, giving them a familiarity with government administration which is useful in their present positions with the A. M. A. Division of Socioeconomic Activities. Inquiries related to medicine come from many sources. A West Coast physician is concerned over the medical care of migrant Mexican laborers. One of the physicians in Washington contacts the Labor Department on the matter. A midwestern congressman inquires whether a widely publicized drug offers any hope for a dying constituent. The lawmaker is informed of scientific findings on the drug. From a local medical society comes a report that a federal agency is infringing on private practice. Investigation shows that patients are being treated only as part of a research project.

James W. Foristel is one of three A. M. A. legislative representatives.

While Drs. Jobe and Anderson are concerned mainly with the administrative agencies, other members of the Washington staff follow congressional activities. Dr. Lester says the A. M. A. actually spends about one-third of its effort in the city in the legislative field, much less than many persons would suppose.

As many as 20,000 bills and resolutions may be introduced in a single session of Congress. They are analyzed by Washington staff member Paul R. M. Donelan, attorney in the A. M. A. Law Division, for any significant application to medicine. Proposed legislation in this category is channeled to the A. M. A. Council on Legislative Activities for study. The Council then recommends an A. M. A. position to the Board of Trustees. When congressional hearings are held and the Association is to submit statements or testimony, Washington office personnel assist witnesses who will speak for the A. M. A.

When the Association takes a stand on legislation, more often than not it is in favor of what is being proposed. The positive record of the A. M. A. was cited at its Annual Meeting a year ago to disprove charges that the organization has been basically negative in its attitude. In the 85th Congress, 15 bills of a medical nature were enacted into law and only one was opposed by the A. M. A.

Last year, in the first session of the 86th Congress, the Association submitted 22 statements to congressional committees. Only one was in opposition—on the Forand proposal to expand social security provisions to include hospital, nursing home, and surgical services for beneficiaries aged over 65. Twice representatives of the Association appeared before the Senate subcommittee on problems of the aged and aging to discuss medicine's activities in this field. On other occasions, the A. M. A. reiterated its support of the Hill-Burton program, endorsed a bill on automobile safety devices, supported regulations to protect consumers against hazardous household substances, and urged certain increases in research grants.

The Association has three legislative representatives who work with senators and representatives, their staffs, and the staffs of legislative committees that consider legislation of interest to the medical profession. The three, working through the A. M. A. Field Service Division, are James W. Foristel, Cecil B. Dickson, and Harold Slater. Mr. Foristel, with the A. M. A. since 1948, is a former practicing attorney, administrative assistant to a congressman, and general counsel of the House Small Business Committee. The other two men joined the A. M. A. staff last year and both have extensive experience as news reporters and editors.

Medical news from Washington often has one application for physicians and another for laymen.

Three physicians—Drs. Jobe, Lester, and Anderson—serve in the Washington office.

Ted Lewis checks Michelle Huggard as she teletypes Washington news to the Chicago headquarters.

Both needs are met by Ted Lewis and Dayton Moore, associate editors of the A. M. A. Communications Division. Through personal contacts and the teletype service of one of the major news agencies they keep abreast of day-by-day activities of committees and agencies. Columns are written by the editors for medical publications, including The Journal and the *AMA News* (published in Chicago and the successor to a newsletter formerly issued directly from Washington). The editors also handle relations with medical writers and reporters.

Widely varied activities are centered in the Washington branch—information is gathered from the special library maintained on medical legislation, mimeographed material is prepared for speeches and testimony, assistance is given visiting delegations from state medical societies. Yet the A. M. A. was in existence for nearly a century before it opened a permanent office in the nation's capital in 1944. The House of Delegates voted in 1950 to strengthen the office and a year ago it was reorganized for a closer coordination with Chicago.

Work of the Association often extends beyond national borders. Speaking before a Senate committee last year, Dr. Gunnar Gundersen, then A. M. A. President, said there is "a growing recognition that medicine, with its resources and influence fully mobilized, can perhaps do more for world peace than billions poured into armaments. There is a mounting conviction that the time has come when medical statesmanship must be used to augment the methods of political diplomacy."

The Federal Physician—His Future In the A. M. A.

Physicians in federal service now number about 17,500, five times the figure of a quarter century ago. What will be their future relationship to the rest of the medical profession?

In search of the answer, the American Medical Association's Committee on Medical Facilities spent Jan. 9 and 10 in Washington, D. C., where concentration of government doctors is especially high. For the past two years the Committee has been making a study to determine whether A. M. A. should revise its membership requirements to meet changing conditions in medical practice and American life generally. The study is concerned not only with federal service physicians but also with those in teaching, research, insurance, hospital work, and other types of nonprivate practice.

Dr. Willard A. Wright, Chairman of the Committee, promised that its report will be submitted to the Council on Medical Service in time to be ready for the House of Delegates in June.

Historically, most of the physicians in the United States have been in private practice and A. M. A. membership has centered on the local societies. Today, however, of all doctors active in medicine, one in every three is in nonprivate practice.

The number of active physicians rose from 150,419 in 1931 to 228,658 in 1959, while the percentage of those in private practice dropped from 86 to 68, according to surveys taken in those years. In the same period, the number of physicians in general practice or a part-time specialty dropped from 112,116 to 83,160. The number in a full-time specialty rose from 22,152 to 78,532. The number in nonprivate practice rose from 16,151 to 66,966, including those in federal employment.

Should a local medical society meet the needs of both the private practitioner and the government physician? To find the answer the Committee met with representatives of medical societies of the District of Columbia; Montgomery County, Maryland; and Arlington County and Alexandria, Va.

All Agree on Goal

Dr. Wright noted that in previous meetings the Committee had found that "Everyone agrees the A. M. A. should represent all doctors, whether they are in private practice or not." There was no objection to this ideal from the local society representatives. One of them observed, "We are all physicians; we are all working toward the same goal."

Representatives of the local societies, however, cited some practical difficulties in admitting any large portion of the federal doctors as members. They frequently stay in one community only a short time. They have little direct interest in some of the society's services to the locality in the areas of public forums, mental health, public health, and guidance. They may share an interest in scientific programs but not in the problems of private practice.

The Committee noted that lack of a license is the most frequent technical reason why a physician is disqualified from membership in a society. Other reasons may be inadequate period of residence in the community and the type of practice in which the physician is engaged.

A separate conference was held with medical officers of the U. S. Army, Navy, Air Force, Public Health Service, and Veterans Administration. Most physicians in these branches now hold a service membership in A. M. A., given to them free, without requirement of membership in a local society and without voting privileges. Would these doctors want to trade their present status in A. M. A. for regular dues-paying membership?

Keeping the present policy was favored by most of the medical officers who conferred with the Committee. They said the service membership often provides a pleasant introduction to organized medicine for the young doctor before he is permanently settled. The present arrangement also was said to allow for considerable professional and social contact between doctors in military service and local medical societies.

How is A. M. A. to serve all physicians equally well? The problem, predicted one Committee member, will be solved in time. "But the solution cannot be imposed from the top. It must come from the local society."

Dr. Willard A. Wright of Williston, N. D., is Chairman of the A. M. A. Committee on Medical Facilities. Other members are Drs. William F. Costello of Dover, N. J.; Charles L. Hudson of Cleveland; Robert L. Novy of Detroit; David H. Poer of Atlanta; John M. Rumsey of San Diego, Calif.; W. C. Stover of Boonville, Ind.; and Walter E. Vest of Huntington, W. Va. Dr. Edward C. Rosenow Jr. of Philadelphia is a Committee consultant and Mr. George W. Cooley of Chicago is staff secretary.

Doodlebug's Delight

Specialization, the medical motif of the 20th century, has extended even to parking lots.

One such transportation terminus, at the rear of the Multnomah County (Oregon) Hospital, has been set aside solely for the storage of compact foreign or American cars. According to Dr. Jarvis Gould, assistant administrator at the hospital, the experiment has been a success, and the capacity of the formerly 22-car lot has been raised by 4.

The hospital was backed by precedent, however. The University of Oregon Dental School once had a space devoted only to the parking of motor scooters.

Cooperation Marks Prison's Medical Care Plan

Why do many prison inmates readily volunteer for experiments in medical research? "The same reason you would," says Warden Douglas C. Rigg of Minnesota State Prison, at Bayport. "The only way medical science can advance is through public cooperation. Some persons donate money, some blood, some time, and some help in this way."

Two years ago Warden Rigg worked out a prison medical care program with the University of Minnesota Medical School and Mount Sinai Hospital in Minneapolis, a teaching hospital for university medical students. Research, although incidental to the program, has been conducted in various fields.

Warden Rigg estimates that 700 inmates have participated voluntarily in experiments. Since the prison population is about 1,300, the rate of participation is high, even considering the turnover and the fact some men volunteer more than once.

Before the medical care program was worked out, Warden Rigg says, the prison had difficulty in employing physicians. Now this need is filled by two medical residents—one in internal medicine and one in surgery—who are assigned to the institution for a six-month period and are on call at all times. They work under the supervision of physicians in the medical school.

The prison's program, which Warden Rigg says was started to meet the health needs of prisoners, has developed into a threefold benefit: Care for inmates, training of young doctors, and service to humanity.

Auxiliary Project Produces Better Baby Sitters

Parents in Seattle and King County, Washington, should have less difficulty these days finding a qualified baby sitter. More than 5,000 of the area's teenagers attended child-care classes last year.

Physicians, who often hear of emergencies caused by inexperienced child tenders, donated their time for the classes, held in junior and senior high schools. The course was started four years ago by the Seattle-King County Safety Council and the Women's Auxiliary to the King County Medical Society. In the present school year free time is being donated by seven doctors and one doctor's wife, Mrs. William Halliday, president of the Nurses' Alumni of the University of Washington.

Girls may use the information either in caring for someone else's children or in caring for their own, later in life. The program also helps the medical profession build better public relations.

The students are taught the dangers of sharp toys, small objects, poisons, and hot food. They learn how to change and bathe a baby safely and how to put him to bed. The instruction also stresses the responsibilities of parents in the selection of the sitter and the leaving of special instruction and emergency telephone numbers.

Similar programs have been conducted in many other cities, with use of kits supplied by the National Safety Council. The trainees are called Good Emergency Mother Substitutes, or GEMS, a gauge of the value of the qualified sitter.

Calling the Doctor—Via Short-Wave Radio

From an amateur's toy of the recent past, short-wave radio is today a communication medium of tremendous economic importance. From taxicabs to trash trucks, and from steelmakers to security officers, Americans are making increasingly greater use of the band of radio frequencies that compose the short-wave spectrum.

Physicians, too, have eyed such communications with interest, but in many cases they have been disappointed by services that failed to measure up to their promise. It was for this reason, two years ago, that the American Medical Association, on the advice of its Committee on Radio Communications, petitioned the Federal Communications Commission for 12 frequencies for exclusive use by a Physicians' Radio Service. Since then the American Hospital Association has also petitioned for five frequencies for hospital purposes.

If the A. M. A. petition is successful in having the requested frequencies set aside for the exclusive use of physicians, it will allow professionally established, two-way radio services for all physicians desiring to subscribe. It is expected that such services will be supplemented by standard telephone and radio paging systems, depending on the type of service desired.

Last November, the FCC issued a proposed list of frequency allocations which, if followed, will set aside a total of 17 frequencies for transmission

The Squawk Box

The number of usable short-wave radio frequencies is limited, and the demand is heavy. These facts make it necessary for radio users to share frequencies. Low transmitter power and geographical separation usually preclude interference.

There are times, however, when things go wrong, as they did one day when the office receiver of a suburban Chicago water company began issuing strange commands. The superintendent spent a puzzling afternoon until it became apparent that he was receiving signals from vehicles engaged in an oil company test run in Utah instead of reports from his own repair trucks. Unusual atmospheric conditions were blamed for the odd reception.

of "urgent messages essential to the medical duties of the licensee . . . or essential to the efficient rendition of hospital or ambulance service." The FCC requested that interested parties file comments by Feb. 1 on the proposed frequency allocation and that these comments offer advice to the commission on the matter of further subdividing the allocation to separate physician, hospital, and ambulance calls.

If the proposed frequency allocation is granted, such networks will have a secondary use in addition to their day-to-day function—they will make an effective emergency system for rallying and coordinating medical efforts to alleviate the effects of natural or military disaster.

Health and Hobbies—Natural Combination in Cleveland

Physicians—like ministers, insurance salesmen, and mothers of small boys—are often accused of not practicing those things that they preach. This is considered to be especially true of the harried modern doctor who supposedly prescribes a hobby for every patient, but who can never find the time for one himself.

Unless the physicians of Cleveland differ greatly from their colleagues, however, the theory has little foundation. For not only do Cleveland's physicians enjoy numerous hobbies, but they have also exposed them to public view in a show last fall at the Cleveland Health Museum. Sponsored jointly by the Museum and the Cleveland Academy of Medicine, the show offered no awards, nor did it stimulate any competition. Its chief objective was to demonstrate what even time-pressed people can do for relaxation.

Although many of the medical hobbyists stuck to the usual arts-and-crafts pattern, some added unusual modifications and others pioneered. One doctor displayed pen-and-ink drawings on mental disease, which had served as illustrations for his hand-printed book "A Psychiatrist's Anthology." Another submitted a hooked rug, and a third a rebuilt Rolls-Royce.

Dr. Bruno Gebhard, the museum's director, thinks the show was a success. He writes, "One of the chronic complaints in this age of atomic anxiety seems to be 'I would like to do something along this line, but I don't have time.' By putting on a physicians' Hobby Show—physicians being recognized by the public as being a little busier than the average person—the Hobby Show proved quite effective in counteracting this argument."

The *Cleveland Plain Dealer* agreed. It stated, "If hobbies help relieve the tensions of their exacting profession, wouldn't a hobby be a good thing for any man?"

Colleagues Everywhere—A New Life for Old Journals

Some people send CARE packages, others "adopt" foreign children, but in a small town in Western Pennsylvania, a semiretired otolaryngologist mails out letters by the score as his contribution to world betterment. But the letters don't go to foreign countries; instead they go to American physicians who have expressed an interest in a new plan called "Colleagues Everywhere."

Colleagues Everywhere is a program originated by Dr. Charles B. Daugherty of Jeannette, Pa., and is the essence of simplicity. He suggests that, instead of being sold as waste paper, medical journals be given a second life by being mailed to physicians in foreign countries. His logic is this:

Physicians in many parts of the world are without any great amount of current medical literature, and since English has largely replaced German as the medical language of the world, American doctors with their vast amounts of such literature are in a position to make a contribution to foreign medicine for the cost of re-mailing old journals.

To put his plan into effect, Dr. Daugherty needed two lists: one of foreign physicians to whom the material could be mailed and one of American doctors willing to take on the job of mailing. The Pennsylvania physician got a start on the first list when he discovered a woman who could furnish the names of a number of doctors in India. With this as a start, he then began writing to nearby physicians, asking that they volunteer to take part in the project. Requests went to members of his own hospital staff, the membership of the Western Pennsylvania ENT Society, and the rolls of his county medical society.

By this time, Dr. Daugherty began to worry about replenishing his supply of potential recipients, and it was then that he struck gold. A chance conversation put him on the trail of a college group interested in a similar but less scientific project. Learning of his need, the group offered to furnish him with the names of as many as 250,000 foreign physicians in 22 countries.

Thus armed, Dr. Daugherty is now seeking converts to his plan. The Westmoreland County Medical Society has agreed to sponsor the program and has offered the use of its office space. The women's auxiliary to the Medical Society of the State of Pennsylvania has become interested, and several state and county medical society publications have published explanations of the idea.

Cost of participation in the project is slight. A mailed request to Dr. Daugherty at 603 Clay Ave. in Jeannette will bring an interested physician the name of a foreign doctor. Then for amounts varying from 14¢ to 24¢, medical journals may be mailed under the rate for printed matter to overseas destinations.

In assessing the first nine months of his efforts, Dr. Daugherty says, "The response has been good but not overwhelming, so that up to now I have been happy to handle it from my own office. To date, I have 65 doctors mailing to 83 overseas colleagues."

One reason Dr. Daugherty urges widespread participation in CE is that he visualizes it as a deterrent to the spread of communism. He says, "Doctors in some of these situations are the only literate persons in their communities and have great influence. If we can get an individual doctor to say 'America is good,' the whole community will say 'America is good.'"

Conclave in Chicago To Promote Home Care

In years past, care at home was what the patient got when he could not or would not go to the hospital. Today, an expanded concept called Home Care is being offered as a partial answer to the need for economical care with a high rehabilitative potential for the chronically ill.

In hopes that this concept—if properly nurtured—will bloom more profusely in the future, five of the nation's major health groups will hold a three-day conference in Chicago next April to "develop methods for stimulating the growth and expansion of organized home care." Sponsors will include the American Hospital Association, the American Medical Association, the U. S. Public Health Service, and the Blue Shield and Blue Cross Commission.

Organized home care programs, while far from numerous, have attained a continuing popularity in recent years. Often they have come into being when a hospital decides to extend the range of its services past its own front doors. Other programs have been developed by such community agencies as health departments or visiting nurse associations. But whatever their sponsorship, they have a common aim—the care, in their own homes, of selected patients who do not require all the treatment facilities of a hospital but who, lacking alternatives, would have to be hospitalized.

Conference invitations have been sent to approximately 50 persons who will represent organizations covering the entire spectrum of health and medicine. They will be assigned to four workshop groups.

Foremost among the source materials available to the conferees will be a preliminary report of a survey of the nation's home care programs. The study will be an updating of a similar effort in 1956, which produced a detailed listing of facts and figures on 31 programs. The number of programs now in existence is still in doubt, but it might well be more than double the 1956 figure.

Civil Defense in Russia— What About CD in the U. S.?

"If you believe the reports, every one in Russia knows how to use a gas mask. . . . every child who passes the sixth grade has had a first aid course."

The scope of civil defense in the Soviet Union was described in these words to a group of midwestern medical society representatives in Chicago, Jan. 23. Dr. Paul A. Lindquist, deputy for operations of the Health Services of the Office of Civil and Defense Mobilization, showed a series of colored slides of Russian civil defense posters.

"All this has taken place since 1955," Dr. Lindquist said. The Russian government, he said, has given two civil defense courses for the entire population and is planning a third phase. "The course includes exposure to a lethal gas for 15 minutes."

The meeting was attended by representatives of state societies in Illinois, Indiana, Michigan, Missouri, and Wisconsin, all part of OCDM Region Six. The meeting is one in a series sponsored by the A. M. A. Committee on Disaster Care to encourage physicians and others in the medical field to help promote the concept of civil defense at the local level. All eight OCDM regions will have been covered when the final meeting is held in Washington, D. C., on April 23 and 24.

Two differing views on the best approach for stirring interest in civil defense were heard in Chicago. Dr. E. P. Ludwig of Wisconsin said the greatest public support for civil defense has arisen when protection against natural disasters is emphasized. "If you don't, people just lose interest," he said. Doctors from other states agreed that earthquakes, tornadoes, fires, and similar catastrophes create more interest in civil defense than do discussions about what would happen in the event of an atomic attack.

Emphasis on the wrath of Nature was called a mistake by Frank O. Starr, director of OCDM Region Four. Mr. Starr said that, while civil defense has a peacetime application, its basic purpose must remain the same: preparing the nation to withstand a wartime attack.

He urged physicians to help combat what he called three widespread fallacies hindering civil defense in the United States:

1. That the military will take over in case of attack. He said the military would help but would lack the capabilities for taking care of the entire nation.

2. That the Soviet Union will not use the hydrogen bomb because it is too horrible. He said past performances and recent statements by leaders of world communism prove it remains a serious threat.

3. That no one could survive hydrogen bomb warfare. He said the survival rate of a nation would depend largely on its civil defense preparations.

FREEDOM OF CHOICE

AT ATLANTIC CITY in June, and again at Dallas in December, the American Medical Association's House of Delegates proclaimed and reaffirmed the belief that the "free choice of physician is the right of every individual" and that such freedom of choice, together with free competition among physicians, constitute prerequisites to "optimal medical care." In so doing the House of Delegates, by inference, took a position in favor of individual freedom of choice in general and expressed a preference for maintaining a social, political, and economic framework in our society conducive to the preservation of such freedom of choice.

All too frequently the term freedom has been misused or abused. Perhaps this is inevitable when the concept of freedom is capable of stirring up considerable emotion in the human breast; indeed, some men have died for it, and many others have proclaimed their willingness to do so. Less often, however, have men had the patience to devote attention to the less emotional and more mundane restrictions on freedom when these do not directly affect them. Certainly it behooves members of the medical profession to give attention to the broader meaning of the term "freedom of choice" and to its implications.

If freedom of choice were to relate merely to the number of courses of action open to a person, it would be more accurately described as power of choice. But freedom of choice represents something more fundamental than power; it represents the right of the individual person to be a free agent in his interhuman relationships, to make his own decisions, to be free from the arbitrary authority of others, and to be able to choose how he wishes to use his services or property rather than to be subject to coercion by others. Freedom of choice means that the person is able to choose his own course of action and his own pattern of living, subject to the requirement that he shall not act so as to violate the freedom of choice of others.

Freedom in this sense, it should be noted, is freedom of, not freedom from or freedom to; the preposition is of great importance, for the latter represent not different aspects of the same thing but entirely different conditions. This calls to mind the famous four freedoms enunciated by President Franklin D. Roosevelt during World War II—freedom of speech, of worship, from want, and from fear—later called "a noble pun" by the British economist, Joan Robinson. The two pairs of freedoms were, in fact, of entirely different character. Mr. Roosevelt meant security from want and fear, not freedom or liberty. Many philosophers, including Franklin and Jefferson, have pointed out that freedom and security are inconsistent human conditions. Indeed, make freedom of choice into freedom from choice and one comes close to a definition of slavery.

The struggle and debate of our time is intimately related to this difference between freedom of choice and from choice. Such a difference relates to the alternative methods of organizing human activity and is not simply a struggle between the United States and the Soviet Union or between the free world and the unfree world. Human activity can be organized so that the individual person has freedom of choice or so that he has little or no choice. The latter is the technique of the totalitarian state while the former is the mechanism of the market place with limited government and the separation of political powers.

A freedom-of-choice society in the economic sphere is a market society. Individual economic transactions are conducted through the voluntary cooperation of reasonably well-informed persons in such a way that both parties benefit from them. A free-choice society provides a mechanism for bringing about coordination with a minimum of coercion. Human activities, so far as possible, are conducted in the market, not in the political sphere. In this way coercion of individual persons to conform is minimized and freedom of individual choice is maximized. Each person can choose the color of tie he wants, the architecture of his house, and the cut of his clothes. He does not have to submit to what the majority wants; he may make his own choice and get it.

This is, of course, exactly the opposite from that organization of society where decisions which could be made by the market are made on a political yes or no basis. Even if these decisions are reached by the expedient of democratic majority rule (which may be transitory) rather than by dictatorial fiat, the political decisions are the results of group pressures instead of individual choices.

We live in a society still essentially free, one that gives to the individual person the right not only to choose his physician but to make other choices as well. Indeed, we have even permitted the individual person to choose to use his capital and his services to advocate the abolition of freedom of choice itself. Throughout the history of mankind this sort of society has not been the general rule but the exception. Perhaps this is inevitable. The totalitarian collectivist principle is simple and straightforward; it appeals to those who say, "Do something now." The necessity of restraint, group and individual, the recognition of ignorance and the imperfection of human knowledge, and the denial of a millennium and the aim of establishing conditions that make life not perfect but workable—all these attributes of a free-choice society constitute a highly sophisticated doctrine.

It is sobering to see the growing number of so-called leaders of political thought or politicians who advocate an ever-growing governmental assumption of responsibility for all sorts of complex economic and social problems—full-employment, care for the aged, care for the indigent, government health services, subsidized housing, and so on and on. Yet the moral ethic on which our civilization rests emphasizes individual responsibility. Can such a civilization survive? Perhaps, but only if it recognizes the difference between freedom of choice and freedom from choice.

LEPTOSPIROSIS IN HUMAN BEINGS

Leptospirosis in human beings is an acute, self-limited illness caused by infection due to pathogenic members of the genus Leptospira. The disease was once considered to be rare in the United States and was diagnosed almost exclusively in the presence of renal damage, hemorrhage, vascular collapse, and other distinctive features of spirochetal jaundice (Weil's disease). It is now known that leptospirosis is widespread in the United States and that most of the patients are neither icteric nor critically ill. Eight different serotypes have been identified with the disease in human beings, and several others are known to infect animals. But despite the increasing awareness of leptospirosis on the part of physicians, there is reason to believe that many cases go undetected each year.

In the literature devoted to leptospirosis there are to be found many descriptions of supposedly specific syndromes caused by different serotypes, but a critical review of published case reports lends little support to the view that the leptospiroses constitute a group of distinctive syndromes. Rather, it is impossible to make a species diagnosis on clinical grounds alone, and the disease should therefore be described as a whole and referred to as leptospirosis rather than one of the many special names, such as canicola fever, swamp fever, or swineherd's disease, which have become so popular.

Basically, leptospirosis is a diphasic illness, with manifestations attributable in the first stage to leptospiremia and in the second stage to the body's immune response to the infection. The onset is characteristically abrupt, and the first four to seven days are marked by high fever, chills, headache, myalgia, gastrointestinal complaints, and conjunctival suffusion. Leptospires can be isolated from both the blood and the cerebrospinal fluid during this phase, but there is no meningeal reaction to the presence of leptospires.

The first stage terminates with defervescence and symptomatic improvement, but 12 to 72 hours later there is recurrence of fever and development of meningitis. Fever is usually of brief duration, and meningitis may be either subclinical or overt. Because the spinal fluid becomes sterile shortly after the onset of meningitis, the meningeal reaction of this phase can best be explained as the expression of an antigen-antibody reaction. Hypersensitivity has also been suggested as the basis for the neurological lesions which sometimes develop after the first week. Uveitis and leptospiruria are also features of this stage, but their pathogenesis differs from that already mentioned. They result from the proliferation of leptospires in organs where the concentration of antibodies remains very low—the anterior chamber of the eye and the tubule of the kidney respectively.

The prognosis in anicteric leptospirosis is excellent, regardless of therapy, but an appreciable mortality continues to result from spirochetal jaundice. This syndrome should no longer be regarded as a synonym for Leptospira icterohaemorrhagiae infection since the distinctive features of spirochetal jaundice can result from infection by any highly virulent leptospire, regardless of serotype. The term is useful for descriptive purposes, however, and should be retained.

The epidemiology of leptospirosis is now well understood. Man, an incidental and nonessential link in the maintenance of leptospirosis in nature, acquires infection either directly from the infected urine or tissues of affected animals or indirectly through contact with contaminated soil or water. The most frequent source of infection is stagnant water which has been contaminated by the urine of either domestic or wild animals. The portals of entry into the body are abraded skin and the externally accessible mucous membranes.

There is no conclusive evidence that antibiotic therapy appreciably alters the course of leptospirosis, despite the effectiveness of several agents in experimental leptospirosis. It is generally agreed, however, that therapy must be instituted quite

---

Edwards, G. A., and Domm, B. M.: Human Leptospirosis, Medicine, vol. 39, Feb., 1960.

early in the course of illness if there is to be any benefit. Greatest effectiveness in treatment has been claimed for therapy with the tetracyclines.

The laboratory techniques for the diagnosis of leptospirosis are dependable, but, unfortunately, they are cumbersome and expensive and few laboratories are equipped for them. Several simplified tests are being studied, and, should one or more of these prove to be reliable, serologic testing for leptospirosis should become a standard procedure in public health laboratories.

REQUIREMENTS FOR AN IDEAL THROMBOLYTIC AGENT

At present, thromboembolic diseases represent a major cause of morbidity and mortality. An important therapeutic advance in the management of these problems was achieved by the introduction of anticoagulants. However, their use is designed to restrict extension of an already existing thrombus or to diminish the incidence of new thrombi or emboli; they have little, if any, effect on the immediate consequences of an acute thromboembolic episode. For this reason, much attention is being given to the development of thrombolytic (clot-dissolving) agents which could effect the rapid resolution of thrombi or emboli acutely formed within the vascular tree. Restoration of the circulation through the affected vessel might then limit the damage caused by vascular obstruction, and dissolution of the clot would remove a source of further embolization.

This new approach seems entirely feasible since fibrin, the major insoluble constituent of the clot, is susceptible to enzymatic lysis, and agents capable of effecting such enzymatic lysis may be expected to be delivered to the site of the obstructing thrombus after their introduction into the general circulation. Thrombolytic therapy, then, is based on the principle that thrombi can be dissolved enzymatically if the circulating plasma is endowed with an increased clot-dissolving ability for a long enough period of time. Sound evidence to support this contention has been obtained from laboratory studies, animal experiments, and, most recently, from controlled observations in man.

The problem of developing agents for practical therapeutic use is not simple, since a number of basic considerations must be satisfied. Lack of their recognition often results in unnecessary trial and error, as illustrated by an article appearing in this issue of The Journal, pages 912-915. The following basic considerations are most pertinent to the development of a safe, practical, and effective form of thrombolytic therapy.

1. The thrombolytic agents should have specificity for effecting the dissolution of fibrin but have relatively little effect on other circulating constituents. Proteolytic enzymes which act indiscriminately on a wide variety of plasma proteins cannot be expected to produce thrombolysis without hazardous consequences in other parameters.

2. It must be demonstrated that the administration of the thrombolytic agent induces increased plasma clot-lysing activity of the requisite degree; simple and rapid laboratory procedures should be available for showing that this activity has been produced and sustained in the patient's circulation during treatment. Frequently, the former has not been achieved, and reliable laboratory tests required for this purpose are still of an undesirably complex nature.

3. Thrombolytic agents should be properly standardized, and a technique should be made available for estimating the dose required for any particular patient. Current standardization for these agents is still unsatisfactory, and relatively little attention has been given to the differing abilities of patients to inhibit these agents.

4. The thrombolytic agents should not produce such undesirable side-effects as chills, fever, and hypotension—reactions which plague most of the preparations under current investigation. Though it may be argued that a severe pyrogenic reaction is small payment for the rescue of a doomed limb, it is unlikely that adequate thrombolytic therapy can be sustained in the presence of such a reaction, and the success of other procedures may be jeopardized by the time lost. Furthermore, since patients treated with these agents often will be critically ill, for example, after a coronary or cerebral occlusion, a severe pyrogenic or hypotensive reaction may result in a fatality. Such reactions with biological preparations are usually attributable to pyrogenic contaminants, and appropriate purification could eliminate this hazard.

Thus, an ideal thrombolytic agent would be a specific for effecting clot dissolution, adequately standardized, and capable of being given to patients without significant hazard, and it should be possible to estimate and control the dosage on the basis of simple measurements made on the patient's blood. In this respect, the development of some thrombolytic agents is more advanced than others, but clinically effective thrombolytic therapy, readily applicable to patient care, still awaits practical solution of all the problems raised. None of these problems is insurmountable; indeed, partial answers exist for most, if not all, of them.

The clinical needs for effective thrombolytic agents are so great that crash programs have been considered for their development. It would seem wisest to concentrate support on those studies aimed at rapidly solving the existing fundamental problems, for, immediately on their solution, this new and exciting field of therapeutics will develop quickly and spontaneously at the clinical level.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

Is there anything really sacred about recent predictions that the United States must maintain a specific physician-population ratio or the health of the nation will be in jeopardy?

I hope not. To me such a figure is merely a projected ratio which is a combination of current birth rates and population factors compared to output of new physicians and existing doctor supply. Hidden in the projected ratio is the assumption that our present experience with all these factors will continue through the next decade or beyond. By using the latest figures on physicians and population and by using estimates of the population of the United States in the years ahead, the ratio makers have shown that there is an increasing need for a stepped-up output of physicians through the next few decades.

Let me hasten to emphasize that I concur that an increase in the physician population will be necessary. Indeed, the number of physicians has risen steadily for many years. As the future market for medical care increases, I believe that physician population will rise to meet this desirable market demand. Contrary to the vocal opinion of some, medicine is not attempting to regulate supply. The record will show that medicine has welcomed and encouraged the training of more physicians.

I feel that too much stress can be placed on physician-population ratios and on the need to maintain the same ratio through the years. Is there really any reason why the nation should be bound to a rigid ratio?

It is my belief that projected ratios rely too heavily on factors that are not easily predicted—future birth rates and developments in medical science. I think that a significant development in population behavior or in medical science might occur which would reduce or increase the demand for physicians substantially in 5, 10, or 20 years.

I am confident that the general level of physician productivity and efficiency will rise considerably even though medicine becomes more complex. For example, space research is certain to give medicine fantastic new procedures in diagnosis and in health maintenance. New drugs also will enhance the effectiveness of medical care and treatment. A third major factor will be the extent to which paramedical health personnel is used.

Medical care today is not supplied only by a physician and the services he renders. The paramedical group now contributes extensively as a medical team member to a patient's care. In the first half of the 20th century the number of physicians increased 60%; in the same period the number of personnel in health services rose at least 400%. It is probable that in the remainder of the century health personnel will make comparable gains.

Furthermore, despite the new trends in population—more aged and more young people who need more medical attention—I believe that persons in the United States may require less medical care as the years go by. The number of "well" persons will grow as the general level of education rises, as more persons become sufficiently interested in their health, and as they take advantage of preventive medicine.

Thus, a physician-population ratio may be somewhat interesting, but it is merely an empirical relation between the number of physicians and the number of people. It is nothing more.

Louis M. Orr, M.D.
Orlando, Fla.

COUNCIL ON MEDICAL SERVICE

The Committee on Maternal and Child Care of the Council has reviewed the following report and endorses such activity. The Committee commends these two committees for their work in Illinois and suggests that this approach to a specific major cause of maternal mortality and morbidity may well be considered in other states.

CLINICAL REVIEW OF BLOOD LOSS IN 13,025 DELIVERIES IN THE STATE OF ILLINOIS

Almost five years ago the Illinois Gynecological and Obstetrical Society, through its committee on obstetric hemorrhage, undertook a unique project in clinical research at the grass roots level. Generalist and obstetric specialist members of the society alike have made a concerted effort to learn more about the causes, management, and prevention of excessive obstetric blood loss.

TABLE 1.—*Four-Year Summary of Operations of Joint Committee on Hemorrhage*

Yr	Cases Reviewed, No.	Av. Blood Loss, Cc.
1955	1,879	214.0
1956	1,428	184.0
1957	3,232	184.0
1958	6,486	175.5
Total	13,025	189.7

Simultaneously, under its chairman, Dr. Frederick H. Falls, the Maternal Welfare Committee of Illinois State Medical Society enthusiastically participated in the undertaking through its hemorrhage committee. Valuable consultation in preventive medicine was fully given by the deputy director, Dr. Don Rawlings, of the Division of Preventive Medicine, and the obstetric consultant, Dr. John Rendok, of the Bureau of Maternal Health, Illinois Department of Public Health. They contributed immeasurably to our joint accomplishments and plans for long-range objectives.

Over the years 1954-1958, statistical information (tabulated below) was supplied by Illinois physicians volunteering in this study. These physicians represented geographical areas outside the city of Chicago. The tables presented in this report are summaries made by the committee after careful study of information supplied them by their colleagues practicing in small towns and metropolitan areas alike.

At each annual meeting of the Illinois Gynecological and Obstetrical Society, the membership received a current report of the committee's work as a part of the regular agenda. Interest and enthusiasm have mounted over the years, stimulating the committee to enlarge its scope in accumulation and interpretation of data.

Table 1 shows the number of cases submitted by years. The estimated or measured blood loss is tabulated. Physicians submitting the data arrived at their figures either by actually weighing all linen soiled in delivery and extrapolating the quantity or by measuring blood collected in the basin placed against the perineum and estimating the blood on linen and sponges used. Whatever error exists with this simple procedure is probably a fairly constant one.

TABLE 2.—*Form of Initial Work Sheet*

To be mailed to: Dr. John Doe ________________ Hospital
0000 Main St. ______ Month of ______ 1958
Middletown, Ill.

Statistical Study for the Maternal Welfare Committee
Illinois Obstetrical and Gynecological Society

Patient, No.	Estimated Measured Blood Loss, Cc.	Gravida	Spontaneous or Induced Labor?	Type of Delivery	3rd day Hemoglobin Level	Was Cervix Examined or Visualized Before Removal from Delivery Room?

A statistical work-sheet was adopted for survey in 1958 (table 2). Table 3 is a completed summary of the 6,486 cases studied in 1958. Note the increased number of items tabulated.

Encouraged and inspired, the committee believed it should attempt to learn more about what happened to the babies in these cases. Thus table 4, the form sheet adopted for 1959, indicates our initial step in a clinical approach to neonatal deaths and allied casualties. With provision for three additional items of information, it is possible that our study may assume greater status as a pattern for obtaining data.

Conducted by Hemorrhage Committee, Illinois Gynecological and Obstetrical Society, and Hemorrhage Committee of Maternal Welfare Committee, Illinois State Medical Society. Members of these two committees who have contributed to this work are Drs. Willard C. Scrivner, Chairman; V. B. Adams; Ray Bucher; Carl Greenstein; A. B. Owen; Ralph Redmond; A. E. Ahlm; Hubert Allen; E. C. Bucher; A. R. Esposito; J. M. Kowalski; Howard Penning; and Worling Young.

Summary and Conclusions

This study in clinical work has been completely voluntary by all participants. There is, no doubt, error in method of estimation and measurement of blood loss but, we hasten to add, these are probably constant errors and do not affect trends indicated by the study. As a result of this and other efforts, we believe hospital obstetric personnel are more alert in anticipation, prevention, and treatment of excessive obstetric blood loss. As an added reminder, there is displayed in a conspicuous location in the delivery room of each Illinois hospital an enlarged plaque in red, white, and black, entitled "Dial for Safer Hospital Obstetrics."

* These quantities were reported as percentages of normal (normal for women, 12-16 Gm.%).

Objectives for the future are as follows: 1. To secure additional significant information along the lines we have conducted our past studies. 2. To evaluate and use data furnished by our colleagues for constructive purposes. 3. To emphasize anticipation, prevention, and definitive management of excess obstetric blood loss. 4. To make available the fruits of our endeavors to the education of medical personnel and those in associated disciplines. 5. To assist in successful education of the public to their responsibility in maternal and child welfare. 6. To develop acceptable and practical avenues of pursuit to assess ourselves in the prevention of infant deaths and associated casualties. 7. To develop closer relationships with fellow physicians in other states who have conducted or who wish to inaugurate a similar program.

A. M. A. GRANTS-IN-AID FOR RESEARCH

The Committee on Research of the A. M. A announces that the subcommittee on Grants-in-Aid is prepared to make grants up to $500 in 1960 to supplement clinical and basic medical science research. Grants will be made for the purchase of supplies, animals, and equipment but are not intended for the payment of salaries of full-time or part-time secretarial or technical help, labor, or overhead. No more than two awards will be made to any one institution. The tentative closing date for the receipt of applications has been set for April 1, 1960. More complete information concerning the program and application blanks may be obtained by writing to the Secretary, Committee on Research, American Medical Association, 535 N. Dearborn St., Chicago 10.

MEDICAL NEWS

COLORADO

Institute for Cancer Research.—Ground was broken recently for the two-million-dollar Eleanor Roosevelt Institute for Cancer Research at the American Medical Center, Denver. The dedication speech was given by Arthur S. Flemming, Secretary of Health, Education, and Welfare. Senator Richard L. Neuberger, Oregon, was also a speaker. The research unit will draw patients from the American Medical Center, a nonsectarian center founded in 1904 as the Jewish Consumptives' Relief Society. The center changed its name and began taking in cancer patients about five years ago. It is privately financed and offers free and unlimited care to patients for all stages of cancer. The research director of the institute will be Dr. Robert A. Huseby, of the University of Colorado School of Medicine.

ILLINOIS

Student Health Center.—Ground-breaking ceremonies for a new one-million-dollar student health center at Northwestern University were held Wednesday, Feb. 10, in Evanston. The new building, to be named the Searle Student Health Center, was made possible by an $800,000 gift from John G. Searle, vice-president of the university's board of trustees and president of G. D. Searle & Co., Chicago medical research and pharmaceutical manufacturing organization. The two-story health center will contain out-patient clinical facilities and general offices on the main floor and a 44-bed infirmary on the top floor. The level below the main floor will contain a small dining room, a nurse's lounge, a special laboratory, and classroom and storage space. The first floor will also contain a medical library which will house a collection of references concerning the health and psychological problems of young adults and will serve as a conference room for the health center staff. Completion of the building is scheduled for April, 1961.

Chicago

Nobel Prize Winner to Be Guest Speaker.—The British scientist, Sir Hans Krebs, will be special guest speaker at a symposium on ketosis to be held at Presbyterian–St. Luke's Hospital Wednesday, March 2. The symposium, which will include talks by specialists from across the country, is being held under the joint auspices of Presbyterian–St. Luke's Hospital and Ames Company, Inc., Elkhart, Ind. Sir Hans will present the first Dr. Joseph P. Ross Lecture, to be held at the Drake Hotel Wednesday evening. Title of his lecture will be "The Biochemical Lesion in Ketosis." Discoverer of the Krebs Cycle, Sir Hans is Whitely Professor of Biochemistry, Oxford University, and was Nobel Laureate in 1953. Other topics covered in the symposium will include the physiology of ketosis; ketosis in children; and clinical ketosis in adults. Members of the medical and related professions are invited.

Meeting on Medical Electronics.—Dr. William I. Freud, Skokie, will present "Spatial Vector Electrocardiography" at a meeting of the Professional Group of Medical Electronics, March 11, 8:15 p. m. Cocktails will be served at 5:30 in the lounge on the sixth floor of the Western Society of Engineers, 84 E. Randolph, Chicago. A speakers' dinner will be held at 6:15 p. m. The Professional Group of Medical Electronics is an affiliate group of the Institute of Radio Engineers, which was organized in 1912. The group is concerned with "the advancement of science and engineering leading to increased professional standing in its field and serves to aid in promoting close cooperation and exchange of technical information among its members." It provides a forum for discussion and presentation of papers for subjects of mutual interest. For registration at the March 11 meeting, call Mr. Charles F. Valach at COlumbus 1-2000.

Fund to Memorialize Dr. Carlson.—Efforts to establish an Anton J. Carlson Lectureship were announced by Dwight J. Ingle, Ph.D., chairman of the department of physiology, University of Chicago. Following the death of Dr. Carlson, Frank P. Hixon Distinguished Service Professor, and chairman of the department of physiology, faculty members expressed hope that some suitable means be found to commemorate his name. The suggestion most favorably received was the establishment, in perpetuity, of a distinguished lectureship bearing the name of Dr. Carlson. Dr. Ingle has undertaken the responsibility of raising the funds necessary to provide a "generous annual honorarium" so that the university can invite "the most eminent scientists" to speak on these occasions. Thus far, the appeal has been directed primarily to friends, colleagues, and former students of Dr. Carlson. Dr. Carlson's varied interests led him to make contributions in the areas of medicine, science, and industry; Dr. Ingle, therefore, is extending the appeal to individuals and groups who might welcome the opportunity to honor Dr. Carlson through the university he served.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

Dr. Orr to Speak at Tuberculosis Luncheon.—Dr. Louis M. Orr, President of the American Medical Association, will be the principal speaker at the Tuberculosis in Industry luncheon March 17 at the Hotel Morrison. The luncheon will be held on the closing day of a two-day spring conference sponsored by the Tuberculosis Institute of Chicago and Cook County. Dr. Orr will be introduced by Dr. B. Dixon Holland, Secretary, Council on Industrial Health, A. M. A. The 10th annual conference, planned for doctors, nurses, leaders of industry, educators, and public health workers, will include a report of the last decade in the Chicago tuberculosis battle, an open forum on tuberculosis control, a symposium for patient approach to the tuberculosis alcoholic and his problems, and a report on advances in medical sciences. Dr. Morris Fishbein, medical editor, will speak on advances in medical science at the luncheon on the opening day. Prior to his speech, the Tuberculosis Institute Medal will be awarded. It is presented yearly to an individual selected for "his outstanding contribution to the fight against tuberculosis."

MARYLAND

Appoint Head for Physiology Department.—The board of regents of the University of Maryland approved the appointment of Dr. William D. Blake as professor of physiology and head of the department at the University of Maryland School of Medicine, Baltimore. Dr. Blake comes from Portland, Ore., where he was associate professor of physiology at the University of Oregon Medical School since August, 1952. Dr. Blake received his medical degree from Harvard Medical School, Boston, and served his internship at Presbyterian Hospital in New York City. He was a research fellow in 1948-1949 at the College of Physicians and Surgeons of Columbia University. In July, 1949, Dr. Blake went to Yale University School of Medicine, New Haven, Conn., where he was first instructor and later assistant professor of physiology.

MASSACHUSETTS

Dr. Lombard Cited.—Dr. Herbert L. Lombard, Boston, until his recent retirement director of the division of cancer and chronic diseases, Massachusetts Department of Public Health, was officially cited by the Commonwealth and the medical profession "for his contributions in the fight against cancer." Governor Foster Furcolo made the citation presentation Jan. 20 at the State House at a special ceremony. The citation was awarded "for distinguished service in the cancer field as administrator, research worker, and epidemiologist, for his inspiration to students and fellow workers, for developing and maintaining the highest standards in statistical work, for establishing data on cancer incidence, [and] for helping to make Massachusetts a leader in cancer control." Dr. Lombard won the top award of the Public Health Cancer Association of America in recognition of his "notable achievements" in 1953. He was director when Massachusetts became the first state in the country in 1926 to inaugurate a cancer control program.

University Grants.—Ninety research and training grants totaling $2,301,697 were awarded to the Harvard Medical School, the Harvard School of Public Health, and the Harvard School of Dental Medicine during October, November, and December, 1959, by the National Institutes of Health, Department of Health, Education, and Welfare, and by the National Science Foundation. The grants ranged in amounts from $2,500 to $121,499.

Alumni Hold Dinner Meeting.—The annual dinner meeting of the Tufts Medical Alumni Association will be held on Wednesday evening, March 30, at the Somerset Hotel, Boston. The guest speaker will be Senator Styles Bridges, who will present "Challenges of the Sixties." Dr. Christopher J. Duncan, Brookline, will preside. Dean Joseph Hayman will present "The Dean Looks at the Medical School." President Nils Wessel will also speak. The 25-year class, M'35, and the 50-year class, M'10, will celebrate their reunions at this time. For information, write Dr. Harry Blotner, Secretary, Tufts University School of Medicine, 136 Harrison Ave., Boston.

MICHIGAN

Dedicate Institute for Mental Health Research.—The University of Michigan Medical Center formally dedicated a $1,500,000 Mental Health Research Institute Building in ceremonies at Ann Arbor Jan. 29. Detlev W. Bronk, Ph.D., president, National Academy of Sciences, and Ralph W. Tyler, Ph.D., director of the Center for Advanced Study in the Behavioral Sciences, gave addresses at the dedication. The institute was established in temporary quarters four years ago. Its purpose, which will be accelerated in the new building, is a concerted attack on basic elements of mental illness, a health problem estimated to cost the American people an annual loss of 3 billion dollars and 325,000 man-years. Governor G. Mennen Williams spoke on behalf of the State of Michigan, and Dr. Jack Masur, assistant surgeon general, U. S. Public Health Service, represented the scientific interest of the federal government. State funds provided over three-quarters of a million dollars toward the construction of the research facility, with the balance coming from the U. S. Public Health Service. The McGregor Fund of Detroit contributed $100,000 for special equipment. The institute has a staff of over 60 scientists. The new building, located at the west end of the U-M Medical Center was opened for public inspecition Jan. 30. The structure has three floors of offices, conference rooms, workshops, and laboratories.

MISSOURI

Dr. Menkin Comes to Kansas City.—Dr. Valy Menkin, guest investigator at the Henry Phipps Institute of the University of Pennsylvania, Philadelphia, was appointed professor of pathology and chairman of the department of pathology at the University of Kansas City School of Dentistry, Kansas City. Dr. Menkin started his appointment on Feb. 1.

MONTANA

Eye Bank Established.—The Eye Foundation, of Billings, was recently organized and will function primarily as an eye bank. It has received support from most of the service clubs in Billings, with the Altrusa Club the main supporter and founder. Named to the board of directors are Dr. Charles C. Morledge and Dr. James D. Morrison, of Billings. The Eye Foundation is the culmination of an interest of several Billings service clubs over the past three years and the eye bank will "fulfill a growing need for fresh corneas and stored vitreous in this community." Donor cards and information brochures will be made available to Billings physicians in the future. Information may be obtained by writing to the Eye Foundation of Billings, P. O. Box 703, Billings, Mont.

NEW HAMPSHIRE

Unit for Open Heart Surgery.—A program to provide care for children and adults suffering from diseases of the heart and circulatory systems has been established at the Mary Hitchcock Memorial Hospital, Hanover. This program includes the establishment of an open heart surgery unit and the expansion of research and diagnostic facilities. Dr. Richard H. Cardozo heads the open heart surgery unit. Recent purchase of a heart-lung machine by the hospital was made possible by a grant from the Spaulding–Potter Trust. Additional equipment was obtained through funds provided by an anonymous gift. Permanent members of the cardiac group, besides Dr. Cardozo, are Dr. Donald C. Andresen, director of the cardiac clinic; Dr. Mordecai D. Tyson and Dr. T. Richard Watson Jr., thoracic surgeons; and Dr. Roger E. Weismann, a surgeon specializing in diseases of blood vessels. Dr. Ferdinand J. A. Kreuzer, associate professor of physiology at Dartmouth Medical School, will be a consultant in cardiopulmonary physiology. The program conducted by the hospital will be closely related to the research activities of two affiliated organizations, the Dartmouth Medical School and the Hitchcock Foundation.

NEW YORK

Program for Treating Phenylketonuria.—New York State for the first time will go into the community to provide for children a treatment for the prevention of phenylketonuria, Dr. Paul H. Hoch, commissioner of mental hygiene, announced Jan. 29. The program is being organized on a research basis and will make it possible for physicians throughout the state to secure supplies of the necessary diet for patients if their financial circumstances are such that they require assistance. The diet will be supplied for all children up to the age of 5 suffering from the disease who are expected to respond to the treatment. An estimated 20 new cases of this form of mental deficiency occur each year in New York State, Commissioner Hoch revealed. The operation of the pilot program will be centered at Letchworth Village, Thiells, under the direction of Dr. George A. Jervis. All cases will be reviewed in the project center, Dr. Hoch said, but the general medical supervision of the patient will be in the hands of the family physician. Supporting laboratory services will be provided wherever requested. Information on the service may be obtained from Dr. Jervis at Letchworth Village, Thiells, N. Y.

New York City

Development Plan for Medical Center.—The Columbia–Presbyterian Medical Center announced Jan. 24 a development program requiring the subscription of 50 million dollars, the aim of the first joint appeal since 1928. Preparatory surveys for the program began nearly two years ago. An estimated 35 million dollars is sought for eight building projects. For endowment purposes 15 million dollars is desired to permit selective additions to teaching and clinical staffs and to support essential salary standards. General Lucius D. Clay, a trustee of Presbyterian Hospital, will lead the campaign. He has accepted the chairmanship of a newly created Columbia–Presbyterian Medical Center Develop-

View of a portion of the Columbia–Presbyterian Medical Center.

ment Committee of the two boards of trustees concerned. The development program combines three items in one major building project: an 18-story medical research building toward which William Black, president of the Chock Full O'Nuts Corporation and a Columbia alumnus, recently donated 5 million dollars; a library; and a structure to consolidate and house nonmedical services. These buildings will cost 21.5 million dollars. Seven further projects are a $3,200,000 residence hall for married students, residents, and research physicians; a $2,400,000 renovation of laboratories, classrooms, and lecture halls, and $1,100,000 auditorium; a $2,000,000 rebuilding of the second and fourth floors of Presbyterian Hospital; a $2,000,000 addition to transfer and increase doctors' offices; a $2,000,000 modernization of Babies Hospital; and an $800,000 estimate to centralize equipment for x-ray therapy within a single building. Sites for the new construction already are available within the 25-acre Medical Center.

NORTH CAROLINA

Clinic for Treating Cystic Fibrosis.—A new clinic for children and young people afflicted with cystic fibrosis was organized at the Duke University Medical Center, Durham. The new clinic is headed by Dr. Susan C. Dees, professor of pediatrics, and Dr. A. Douglas Rice, instructor of pediatrics. Working with them are other Duke pediatricians and members of the Medical Center's dietetics and physical therapy staffs. Cystic fibrosis patients have been treated on an individual basis at Duke for a number of years, Dr. Dees said. The new clinic "makes possible a better organization of time and hospital resources on their behalf." The Duke clinic will be held at 1 p. m. on the fourth Monday of each month in the Medical Center's pediatrics department. In addition to Duke pediatricians, a dietician will be on hand to give instruction about special diets, and a physical therapist will instruct patients in breathing and lung drainage exercises. The clinic resources are available to private patients and their physicians and to persons unable to bear the full cost of their medical care.

PENNSYLVANIA

Personal.—Appointment of Dr. Joseph R. Albrecht, Philadelphia, as full-time plant physician was announced by Alan Wood Steel Company, Conshohocken. Dr. Albrecht formerly was associate medical director of Reading Hospital and also had been director of professional services and associate medical director at Hahnemann Medical College and Hospital of Philadelphia.—Dr. Frank B. Metting was named as the Health Officer for the Allegheny County Health Department's Northwest District. He will provide full time medical direction for 31 municipalities and the North Side portion of Pittsburgh. For the past four and a half years, he has been in charge of the medical care and public health program for American Arabian Oil Company in the Dhahran area of Saudi Arabia.—John T. Cowles, Ph.D., professor of psychology at the School of Medicine, University of Pittsburgh, was appointed to serve a three-year term on the Selection Committee for the Senior Research Fellowship program of the National Institutes of Health, U. S. Public Health Service.

Philadelphia

Hospital Publishes Research Journal.—The Germantown Hospital of Philadelphia is having the first issue of its *Scientific Research Journal* published Feb. 15. It will be published periodically and will represent original research and other articles of interest. Hospitals wishing to exchange like publications are invited to write the Editor, Germantown Hospital, Philadelphia 44.

Temple Alumni to Fly to Paris.—Alumni of the Temple University School of Medicine will fly to Paris in two groups Feb. 29 and March 2 for a 10-day medical seminar and vacation trip. More than 120 alumni and their wives are signed for the journey, according to Dr. Robert M. Bucher, dean of the medical school. The alumni will spend two days visiting Paris hospitals and will be special guests at the American Hospital of Paris on March 7 for scientific sessions. Both Temple alumni and staff members of the host hospital will present medical papers. A farewell banquet on March 7 will be presided over by Dr. Henry C. Schneider, president of the Temple University Medical Alumni Association. This is the third consecutive year Temple medical alumni have held such special seminars. Previous trips were made to the Carribean and Puerto Rico.

GENERAL

Meeting of New England Allergists.—The New England Society of Allergy will hold its annual meeting and election of officers Wednesday, March 30, at the Longwood Towers, Boston. An afternoon scientific program will be held from 2 to 5 p. m. The annual business meeting will precede the evening scientific session at 7:45.

Conference on Physical Therapy.—The 37th annual conference of the American Physical Therapy Association will be held at the Penn-Sheraton Hotel, in Pittsburgh, June 26-July 2. The theme of the scientific program is "The Physical Therapist and Industry." The program will serve a two-fold purpose: (1) acquainting members with industrial medicine and (2) pointing up the potential role the profession should play in the field. Physicians, physical therapists, and scientists will participate. For information, write Miss Lucy Blair, 1790 Broadway, New York 19, Acting Executive Director.

Annual Fraternity Meeting.—The eighth annual interim scientific meeting of Phi Lambda Kappa, national medical fraternity, will be held at the Deuville Hotel, Miami Beach, Fla., March 20-27. The five-day program, starting Monday, March 21, will be for the benefit of the general practitioner and will feature papers and symposiums by specialists. Members of the medical and dental professions are welcome. For registration and information, write Dr. Samuel L. Lemel, 1621 Euclid Ave., Cleveland 15.

New Fifty Year Club.—Dr. John H. McCurry, of Cash, Ark., is interested in forming an A. M. A. Fifty Year Club in which membership would be limited to members of the Association who have been in practice 50 years or more. The first meeting of the new club is expected to be held during the annual clinical meeting of the Association in Washington, D. C., in November, 1960. Those who are qualified and desire to join this organization are requested to so advise Dr. McCurry, giving their complete name and address. Dr. McCurry plans to be in Miami at the June meeting to begin organizational procedures and to see any who qualify at this meeting.

Report on Deafness.—About 5,800,000 people in the United States have some degree of hearing loss, including nearly 110,000 who are totally deaf, it is reported by statisticians of the Metropolitan Life Insurance Company on the basis of current National Health Survey findings. Forty out of every 1,000 males have impaired hearing, a rate one-third higher than that for females. The higher rate among males is attributed to their more frequent involvement in accidents and their greater exposure to prolonged intense noise in industry. The relative frequency of hearing impairments rises rapidly with advance in age. From 8 per 1,000 persons under 25, the rate rises to nearly 130 per 1,000 at ages 65-74, and to about twice that figure at ages 75 and over.

Group Formed to Study Headache.—Recently a new society was formed, to be known as the American Association for the Study of Headache. The purpose of this organization is to bring together men who are interested in the study of headache and to allow them to discuss and express their viewpoints on current trends in this field. It is planned to have one formal meeting before the annual meeting of the American Medical Association. An informal meeting was held during the recent Southern Medical Association meeting in Atlanta. Officers include the following: president, Dr. Henry D. Ogden, New Orleans; vice-president, Dr. Walter C. Alvarez, Chicago; treasurer, Dr. Robert E. Ryan, St. Louis; secretary, Dr. Bayard T. Horton, Rochester, Minn.; Dr. M. Martin Tunis, moderator, Montreal, Quebec, Canada.

Society News.—Dr. Daniel C. Riordan, New Orleans, was installed as president of the American **Society for Surgery of the Hand.** Dr. George S. Phalen, Cleveland, was chosen president-elect. Dr. Phalen will take office in 1961. Other officers elected were: Dr. J. William Littler, New York City, vice-president; Dr. Don L. Eyler, Nashville, Tenn., secretary-treasurer; Dr. Robert M. McCormack, Rochester, N. Y., historian. Dr. Julian M. Bruner, Des Moines, the retiring president, was elected a member of the council.——Mr. Robert F. Butts, Birmingham, Ala., business manager of Southern **Medical Association,** was named executive secretary-treasurer of the 14,000 member association. He also retains his duties as business manager. Southern Medical maintains home office-headquarters at 2601 Highland Ave., Birmingham, Ala. Its 54th annual meeting will be held in St. Louis Oct. 31-Nov. 3.

Otorhinologic Meeting in Florida.—The American Otorhinologic Society for Plastic Surgery, Inc., will hold its convention and give a seminar in plastic surgery of the head and neck in Miami Beach, Fla., March 6-13 at the Deauville Hotel. Panels and round-table conferences will include the following subjects: blemishes, scars and keloids, fractures of the face; neck surgery; rhinoplasty; and otoplasty. *The program includes the following papers:*

Dermabrasion, Dr. Nathaniel B. Cole, New York City.
Principles in Treatment of Facial Fractures, Dr. Chester C. Woodburn Jr., Des Moines, Iowa.
Principles in Neck Surgery, Dr. Max L. Som, New York City.
Flexible Technics in Rhinoplasty, Dr. Morey L. Parkes, Los Angeles.
Flexible Technics in Otoplasty, Dr. Louis J. Feit, New York City.

The general business meeting and election of officers will be held at 2 p. m., March 7. Motion pictures of surgical plastic procedures will be shown March 8, 10, and 12. For information, write Dr. Joseph G. Gilbert, 75 Barberry Lane, Roslyn Heights, N. Y., Secretary-Treasurer.

International Nutrition Congress in Washington, D. C.—The fifth International Congress on Nutrition will be held in Washington, D. C., Sept. 1-7. An all-day symposium, "World Food Needs and Food Resources," Sept. 6 will be the main feature of the scientific program. The remainder of the program will consist of seven half-day sessions and panel discussions by invited participants, at which discussions are scheduled as follows:

Evaluation of Nutritional Status in Man.
Effects of Processing and Additives on the Nutritive Values of Foods.

Lipids in Health and Disease.
Animal Nutrition and Food Production.
Nutrition in Maternal and Infant Feeding.
Proteins and Amino Acids in Nutrition.
Three Hours Around the World—New Possibilities in Nutritional Research.

Special programs of 10-minute papers reporting unpublished original research will be presented concurrently with the panel discussions. Exhibits of laboratory instruments, books, foods, and other products will be on display. Visits to selected scientific laboratories are planned for Sept. 7. Simultaneous translations will be provided for the four official languages, English, Spanish, French, and German. For information, write the Secretariat, 9650 Wisconsin Ave., Washington 14, D. C.

Catastrophes in 1959.—Catastrophes—accidents in which five or more persons lost their lives—killed more than 1,400 persons in 1959 or about 150 fewer than in the preceding year, statisticians of the Metropolitan Life Insurance Company reported. In major catastrophes—accidents in which at least 25 people are killed—the loss of life dropped from nearly 430 in 1958 to about 175 last year, an "appreciably lower toll" than in any year since 1941. Four of the five major catastrophes in 1959 involved civil aviation. In February, a plane plunged into the East River in New York City, killing 65; another plane disintegrated in the air in a thunderstorm near Baltimore in May, taking 31 lives; in October a crash near Charlottesville, Va., killed 26; and 25 died when a plane rammed a mountain near Williamsport, Pa., on Dec. 1. The fifth major catastrophe was a series of earthquakes which took place on Aug. 17 in the area of West Yellowstone, Mont., claiming about 29 victims. Motor vehicle accidents were responsible for about two-fifths of the lives lost in all catastrophes last year. Fires and explosions accounted for about one-fourth and civil aviation for somewhat less than one-fifth of such deaths. The remaining fatalities were very largely due to natural catastrophes and to accidents involving military aviation, water transportation, and railroads.

Open Competition for Rehabilitation Award.—The R. D. Grant Company Award competition is open to all persons except members of the boards of governors of the American Congress of Physical Medicine and Rehabilitation, American Academy of Physical Medicine and Rehabilitation, and the program committee of the third International Congress of Physical Medicine. Manuscripts must be in the office of the American Congress of Physical Medicine and Rehabilitation, 30 N. Michigan Ave., Chicago 2, not later than May 2. This deadline will be rigidly maintained. The essay must not have been published previously and will be judged on original work, contribution to knowledge of this subject, and clear exposition of the facts. Contributions should not exceed 6,000 words, and the number of words should appear on the title page. Seven copies of the manuscript must be submitted—two original copies and five carbon copies. No papers will be returned. The winning contribution will be determined by the program committee of the third International Congress of Physical Medicine. All contributions will become the property of the American Congress of Physical Medicine and Rehabilitation and will be released to the *Archives of Physical Medicine and Rehabilitation* for publication. The winning essay will be presented at the meeting of the third international congress. The winner shall receive a cash award of $1,000.

Form Neuropathology Commission.—The Commission for Neuropathology was founded by invitation and in presence of the president of the World Federation of Neurology, Dr. Ludo van Bogaert, in the Salpertiere Hospital in Paris, Oct. 24. Neuropathologists from France, Denmark, Germany, the U. S. A., Norway, Switzerland, Great Britain, Poland, Austria, Sweden, Peru, and the Netherlands became constituting members. Prof. Dr. F. Seitelberger was elected secretary of the commission. Its permanent secretariat is: Institute of Neurology of the University of Vienna (Obersteiner Institut), Vienna 9, Schwarzspanierstrasse 17. The commission "claims independence for neuropathology as a proper medical discipline and emphazises the necessity of independent positions for full-time neuropathologists." It will examine neuropathology and neuropathologists in the different countries, will be interested in the preservation and care of the valuable neuropathological collections in different places. It will aim at giving all interested scientists use of these collections. One of the main tasks of the commission will lie in the "efficacious promoting" of scientific activities of neuropathology. Finally the commission is to be a consultative instrument within the World Federation of Neurology, e. g., for the advance of important projects of investigation. It was decided that an international journal of neuropathology, issued in several languages, would be published. For information, write Professor Seitelberger.

Award for Thesis on Laryngology or Rhinology.—The American Laryngological Association announced that, a sufficient fund having accrued from the Casselberry Fund encouraging advancement in the art and science of laryngology and rhinology, this sum is available in part or as a whole for a prize award. Theses must be in the hands of the secretary prior to Jan. 1 of any given year. The award is a prize of money with accompanying certificate signed by the officers of the association. It may be awarded in whole or in part among several contestants. Eligible contestants may be (1) hospital interns, residents, or graduate students in rhinology and laryngology; (2) an individual with an M.D. degree actively practicing or teaching rhinology and laryngology in the Americas; (3) any scientific worker in rhinology and laryngology. Manuscripts shall be presented to the secretary under nom de plume which shall in no way indicate the author's identity. There shall also be a sealed envelope bearing the nom de plume and containing a card showing the name and address of the contestant which the secretary shall keep. Manuscripts must be limited to 5,000 words and must be typewritten, double spaced on one side of the sheet. The thesis shall not have been published elsewhere. The successful thesis shall become the property of the American Laryngological Association but this provision shall not interfere with publication in the journal of the author's choice. Unsuccessful contributions will be returned. The award, made at the annual meeting of the association, shall be based on originality of material, scientific and clinical value, suitability, and method of presentation as to style, illustrations, and reference. The maximum amount of the award shall not exceed $200.

GENERAL

Warning on Mail Swindle.—Postmaster General Arthur E. Summerfield warned that the "Spanish swindle" mail confidence game, by which Americans have been cheated out of upwards of $100,000 a year, is again being actively promoted against the American public. The "Spanish swindle" mail racket operates as follows: basically, the intended victim receives a personal letter from a supposed banker or other respectable businessman in Mexico which usually reads: "A person who knows you and who has spoken very highly about you, has made me trust you a very delicate matter of which depends the entire future of my daughter as well as my very existence." The delicate matter turns out to be that the writer is in a Mexican jail for bankruptcy. He has, however, hidden away in a secret compartment of a trunk, some $450,000. The trunk is deposited, so the letter says, in a United States Custom House. To get out of jail and obtain the claim check for the trunk and pay other charges, will require $10,000 which the victim will be asked to bring with him to Mexico. In return for his trouble, the victim is promised a third of the alleged $450,000. If the victim is taken in he is told when and where to arrive with the $10,000 in cash. He is shortly relieved of this sum—often at the point of a gun—and is usually too embarrassed to report his loss. There is, moreover, no extradition treaty with Mexico covering mail fraud, and the Mexican courts have held that the victims are as guilty as the swindlers. In its more recent operations, lists were taken from "Who's Who in America" and other leading reference books.

LATIN AMERICA

Pan American Congress in Mexico City.—The next Pan American Medical Association congress will meet in Mexico City May 2 to 11, Dr. Joseph J. Eller, director general of the association, 745 Fifth Ave., New York City, announced. The scientific program, through its 48 different medical sections, will include all branches of medicine and surgery, dentistry, hospital administration, and medical education. New sections added since the last congress include space medicine, hematology, cancer cytology, and a section on general practice. Special panel discussions will incude pharmacology and new drugs, mental diseases, nutrition, relationship of dentisty to medicine, cancer research, sudden deaths, and medical press relations. The congress will also have scientific and commercial exhibits, medical motion pictures, and closed circuit television demonstrations of new techniques. Tours will be arranged to medical institutions by the Mexican Chapter of PAMA. The Pan American Medical Association was organized in New York City 34 years ago by a group of physicians for interchange of medical knowledge and research in the Western Hemisphere. They adopted as their credo: "The practice of medicine has no national, racial, or religious boundaries." For information on the congress, write Dr. Eller at the above address.

FOREIGN

Gerontology Institute in Switzerland.—The first international institute for experimental research into the comparatively new science of gerontology was established at the University of Basle, Switzerland, under the leadership of Prof. F. Verzar. Research work will be concentrated on the aging of the tissues of small animals which ordinarily have a short life span. The institute also will consider the aging of muscular tissues, the aging of nerve tissues, and the feeding of old people. The establishment of this international institute is the result of action begun some time ago in Basle when a research team of men and women specialists held a conference and started a study of gerontology. Other subjects under study include the harmful influence of fat accumulation and overfeeding on the life span, as well as problems concerning the toxic effects of products of metabolism.

Congress on Internal Medicine.—On Aug. 24-27 the sixth International Congress of Internal Medicine will be held in Basel, Switzerland, under the auspices of the International Society of Internal Medicine. Two main subjects form the principal program, "The Enzymic Regulation in the Clinic" and "Pathogenesy and Therapy in the Edema." The following are sub-topics:

Cardiovascular Enzymic Regulation.
Enzymic Regulation in the Liver.
Enzymic Regulation in Bones and Kidneys.

Cardiovascular Mechanism.
Tubular Functions.
Aldosteronism.

Panel discussions are planned on diuretics, nephrosis, and interstitial nephritis. Simultaneous translation for official languages will be provided. An exhibit of new research results is planned. Social functions include a special program for accompanying ladies. For information, write the Secretariat, Sixth International Congress of Internal Medicine, Steinentorstrasse 13, Basel, Switzerland.

Proctologists Meet in Rome.—The second symposium of Proctologica Latina, a society of proctologists of the Latin language, will be held May 13-14 at the Hotel Excelsior, Rome. The society organizes annual symposiums where foreign-language-speaking proctologists are presented as lecturers. For each meeting a panel is held headed by a moderator and four participants from different countries, and the subject varies every year. The program for the second symposium includes the following papers by invited participants:

The Surgical Management of Diverticulitis, Dr. Harry E. Bacon, Philadelphia.
Management of Polyps of the Rectum and Colon, Dr. Guy L. Kratzer, Allentown, Pa.
The Surgical Indications for Primary Resection of the Colon in Diverticular Diseases, Dr. James P. Fleming, Rochester, N. Y.
Treatment of Rectal Procedentia with the Délorme Operation, Drs. Richard M. Alexander, Jack W. McElwain, Sylvan D. Manheim, New York City.
The Clinical Importance of Melanosis Coli, Dr. Bruno Samenius, Goteborg, Sweden.
Poliposis Colonica—Treatment, Dr. Roberto A. Garriz, Buenos Aires, Argentina.

Proctologica Latina is legally established in Paris according to French law. For information, write Dr. G. B. E. Simonetti, Milano—Via s., Raffaele 3, Italy, Executive Secretary.

EXAMINATIONS AND LICENSURE

MEDICAL SPECIALTY BOARDS

American Board of Anesthesiology: *Written.* Various locations, June 24. Final date for filing application was January 10. *Oral.* Miami Beach, April 25-30. Applications already on file. Sec., Dr. Forrest E. Leffingwell, 217 Farmington Ave., Hartford 5, Conn.

American Board of Internal Medicine: *Oral.* San Francisco, March 30-April 1; New York City, Nov. 14-17. Closing date for filing application: Jan. 2 and July 1. *Written.* Oct. 17. Closing date for filing application is May 1. *Oral. Gastroenterology.* Philadelphia, March 11-12. Final date for filing application was January 15. Sec.-Treas., Dr. William A. Werrell, One West Main St., Madison 3, Wis.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. St. Louis, April 10-12. In order to be eligible a candidate must have his application filed at least six months before the examination time. Sec., Dr. Donald D. Matson, 300 Longwood Ave., Boston, Mass.

American Board of Obstetrics and Gynecology: *Part II, Oral and Clinical.* Chicago, April 11-16. Final date for filing application was August 1. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Written.* Jan. 23, 1961. Deadline for filing applications is July 1. *Oral.* San Francisco, May 9-13; Chicago, Oct. 3-7. Sec., Dr. Merrill J. King, Box 236 Cape Cottage Branch, Portland, Maine.

American Board of Orthopaedic Surgery: *Part I,* Nashville, Denver and Philadelphia, Apr. 13-14. Deadline for receipt of applications was Nov. 30. *Oral and Written, Part II.* Miami Beach, Jan. 3-5, 1961. Final date for filing application is July 1. Sec., Dr. Sam W. Banks, 116 South Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Oral,* Chicago, Oct. 3-6. Final date for filing application is April 1. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: Memphis, April 21-23. Final date for filing application is March 7. *Examination in Forensic Pathology.* Memphis, April 22. Final date for filing application is March 7. Sec., Dr. Edward B. Smith, Indiana University Medical Center, 1100 W. Michigan St., Indianapolis 7.

American Board of Pediatrics: *Written.* New York City, January 1961. Final date for filing application is Dec. 1. Administrative Sec., Mrs. Eleanor J. Mitchell, Rosemont, Pa.

American Board of Physical Medicine and Rehabilitation: *Oral and Written.* New York, June 17-18. Sec., Dr. Earl C. Elkins, Mayo Clinic, Rochester, Minn.

American Board of Plastic Surgery: *Oral and Written.* Milwaukee, May 1960. Final date for filing application was January 1. Corresponding Secretary, Mrs. Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8, Mo.

American Board of Proctology: *Oral and Written, Parts I and III,* Philadelphia, Sept. 24. Final date for filing application is June 30. Sec., Dr. Stuart T. Ross, 520 Franklin Ave., Garden City, N. Y.

American Board of Psychiatry and Neurology: San Francisco, March 14-15; New York, New York, Dec. 12-13. *Child Psychiatry.* Chicago, April 25-26. Sec., Dr. David A. Boyd, Jr., 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology: *Examination.* Cincinnati, June 6-10; Dec. 5-9. Deadline for filing applications for the June examination was Jan. 1. Filing deadline for the December examination is July 1. A special examination in Nuclear Medicine (for those diplomates in Radiology or Therapeutic Radiology) will be offered provided there are sufficient applications. Sec., Dr. H. Dabney Kerr, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Oral Examinations (Part II):* New Orleans, Mar. 14-15; Kansas City, Kans., May 16-17, and Los Angeles, May 19-20. Sec., Dr. John B. Flick, 1617 Pennsylvania Blvd., Philadelphia 3.

Board of Thoracic Surgery: *Oral.* May 1960. Final date for filing application was Dec. 1. Sec., Dr. Wm. M. Tuttle, 1151 Taylor Ave., Detroit 2.

American Board of Urology: *Written.* December. *Oral-Clinical.* Chicago, February 1961. Exec. Sec., Mrs. Ruby L. Griggs, 30 Westwood Road, Minneapolis 26.

DEATHS

Allee, Warren Logan Ⓜ Eldon, Mo.; St. Louis University School of Medicine, 1906; member of the House of Delegates of the American Medical Association from 1942 to 1952; past-president of the Missouri State Medical Association; member of the American Academy of General Practice; veteran of World War I; served as president of the Bank of Eldon; died in St. Petersburg, Fla., Nov. 23, aged 77.

Bachmann, George Ⓜ Atlanta, Ga.; born in Mulhouse, Alsace, France, July 18, 1877; Jefferson Medical College of Philadelphia, 1907; at one time on the faculty of his alma mater; from 1910 to 1915 professor of physiology at Atlanta College of Physicians and Surgeons, now known as Emory University School of Medicine, where he was professor and chairman of the department of physiology from 1915 to 1947, when he became professor emeritus; served as assistant dean at Emory University School of Medicine; veteran of World War I; fellow of the American College of Physicians; member of the Phi Beta Kappa, Alpha Omega Alpha, and Sigma Xi; medical director, Georgian Clinic of Georgia Commission on Alcoholism; member of the staff of the Emory University Hospital, where he died Nov. 28, aged 82.

Baldwin, John Francis Ⓜ Tenafly, N. J.; Georgetown University School of Medicine, Washington, D. C., 1932; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; veteran of World War II; member of the staff of Holy Name Hospital in Teaneck and Bergen Pines Hospital in Paramus; in 1957 received a silver jubilee award from Georgetown University; died Nov. 25, aged 52.

Bassett, Maurice Gary, Miami Beach, Fla.; Ohio State University College of Medicine, Columbus, 1926; formerly practiced in Cleveland; died Nov. 25, aged 59.

Bastian, George Leon Ⓜ Manchester, N. H.; Harvard Medical School, Boston, 1904; served on the staff of the Sacred Heart Hospital; died Nov. 20, aged 81.

Bawden, George Stephen, Springfield, Ill.; St. Louis College of Physicians and Surgeons, 1906; veteran of World War I; died Oct. 19, aged 79.

Bieberbach, Walter Daniels Ⓜ Worcester, Mass.; University of the South Medical Department, Sewanee, Tenn., 1904; specialist certified by the American Board of Urology; member of the American Urological Association; fellow of the American College of Surgeons; associated with the Worcester City Hospital, where he died Nov. 26, aged 77.

Bliss, Charles Jay Ⓜ Perry, Kan.; Kansas Medical College, Topeka, 1912; served in France during World War I; formerly served as Jefferson County health officer and a member of the Perry city council and board of education; died in Topeka Nov. 24, aged 78.

Bramkamp, Allan Lewis Ⓜ Banning, Calif.; Medical College of Ohio, Cincinnati, 1899; veteran of World War I; at one time associated with the Indian Service; died Nov. 14, aged 86.

Brenner, Franklin Theodore Ⓜ Quincy, Ill.; Rush Medical College, Chicago, 1895; member of the Industrial Medical Association; fellow of the American College of Surgeons; for many years on the staffs of the Blessing Hospital and St. Mary's Hospital; died Nov. 12, aged 88.

Briscoe, Clarence Elbridge Ⓜ New Albany, Ind.; Kentucky School of Medicine, Louisville, 1903; past-president of the Floyd County Medical Society; served as county coroner; died in the Peewee Valley (Ky.) Sanitarium and Hospital Nov. 23, aged 83.

Burrill, Clarence Dean, Framingham, Mass.; College of Physicians and Surgeons, Boston, 1928; veteran of World War I; died Nov. 23, aged 70.

Calvin, Jessie Carrithers Ⓜ Fort Wayne, Ind.; Northwestern University Woman's Medical School, Chicago, 1895; died in St. Joseph's Hospital Nov. 22, aged 91.

Canfield, Albert Ⓜ Madison, Wis.; University of Minnesota Medical School, Minneapolis, 1943; served on the staff of the Mendota State Hospital; died Nov. 24, aged 43.

Charvoz, Elton Ralph Ⓜ Phoenix, Ariz.; University of California School of Medicine, San Francisco, 1916; past-president of the Maricopa County Medical Society; affiliated with St. Luke's Hospital, Memorial Hospital, St. Joseph's Hospital, and the Good Samaritan Hospital, where he died Nov. 29, aged 69.

Cohn, Irma Stern, Cleveland, Ohio; Ludwig-Maximilians Universität Medizinische Fakultät, München, Bavaria, Germany, 1922; died in the Mount Sinai Hospital Nov. 21, aged 63.

Ⓜ Indicates Member of the American Medical Association.

Duff, Alfred William, Brentwood, Pa.; University of Pittsburgh School of Medicine, 1908; veteran of World War I; served as a physician for the Pittsburgh schools; formerly associated with St. Joseph's Hospital in Pittsburgh, where he died Nov. 23, aged 73.

Ehrlich, Maximilian Charles Ⓜ Long Beach, Calif.; University of Illinois College of Medicine, Chicago, 1920; fellow of the American College of Surgeons; served on the faculty Northwestern University Medical School in Chicago, where he was for many years on the staff of the Chicago Wesley Memorial Hospital; veteran of World War II; died Nov. 22, aged 64.

Elterman, Abraham S., East Rockaway, N. Y.; University and Bellevue Hospital Medical College, New York City, 1910; member of the American Academy of General Practice; died in the Hempstead General Hospital, Hempstead, Sept. 10, aged 71.

Felner, Isidore Israel, Brooklyn; University of Edinburgh Faculty of Medicine, Scotland, 1931; interned at the Trinity Hospital; member of the American Academy of General Practice; died Nov. 10, aged 53.

Ferrell, James Carlton Ⓜ Reno, Nev.; Chicago College of Medicine and Surgery, 1910; also a dentist; for many years superintendent of the Nevada Hospital for Mental Diseases; for 12 years member of the Churchill County Board of Commissioners; died Nov. 29, aged 87.

Gardner, Isadore Kenneth Ⓜ Pittsburgh; University of Pittsburgh School of Medicine, 1921; member of the Association of Life Insurance Medical Directors of America; served as associate medical director of the Lincoln Life Insurance Company; died in the Montefiore Hospital Nov. 21, aged 63.

Guthrie, Austin Lee, Oklahoma City, Okla.; Medical College of Ohio, Cincinnati, 1907; served on the faculty of the University of Oklahoma School of Medicine; veteran of World War I; died in St. Anthony Hospital Nov. 25, aged 76.

Hardy, John Walter Ⓜ Butte, Mont.; Miami Medical College, Cincinnati, 1891; died in Mendon, Mo., Nov. 25; aged 97.

Harris, Joshua Harley Ⓜ Memphis, Tenn.; Northwestern University Medical School, Chicago, 1918; specialist certified by the American Board of Ootolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; on the staffs of John Gaston Hospital, St. Joseph Hospital, and the Methodist Hospital, where he died Nov. 29, aged 69.

Hayden, Walter George Ⓜ Toms River, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1911; past-president of the Ocean County Medical Society, of which he was formerly secretary and treasurer; from 1940 to 1944 served on the medical board of the Selective Service; for 30 years Ocean County Jail Physician; associated with the Paul Kimball Hospital in Lakewood and the Point Pleasant (N. J.) Hospital; died Nov. 20, aged 71.

Holm, Charles Robert Ⓜ Hastings, Neb.; University of Nebraska College of Medicine, Omaha, 1946; interned at Santa Barbara Cottage Hospital in Santa Barbara, Calif., where he was associated with St. Francis Hospital; for two years in military service; died Nov. 5, aged 46.

Holmes, Lemuel I. Ⓜ Miller, Mo.; University of Louisville (Ky.) Medical Department, 1910; died Nov. 26, aged 77.

Huml, Anton Peter, Lake Geneva, Wis.; Marquette University School of Medicine, Milwaukee, 1938; interned at St. Elizabeth's Hospital in Youngstown, Ohio; served a residency at Methodist Hospital of Central Illinois in Peoria; veteran of World War II; died in the Veterans Administration Hospital, Tomah, Nov. 21, aged 47.

Hutchison, James Elder Ⓜ West Hartford, Conn.; Johns Hopkins University School of Medicine. Baltimore, 1914; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; veteran of World War I; consultant in internal medicine, Manchester (Conn.) Hospital and the Institute of Living in Hartford; visiting physician, Hartford (Conn.) Hospital, where he died Nov. 21, aged 70.

Iuler, Carl William Ⓜ Columbus, Ohio; Ohio State University College of Medicine, Columbus, 1926; on the staff of the Mercy Hospital; died Nov. 3, aged 61.

James, Jasper Milton Ⓜ Henning, Ill.; Washington University School of Medicine, St. Louis, 1905; past-president of the Vermilion County Medical Society; died in the Lake View Hospital in Danville, Nov. 20, aged 82.

Jones, Fred Durgin, Springfield, Mass.; Tufts College Medical School, Boston, 1913; also a pharmacist; specialist certified by the American Board of Pathology; for many years medical examiner for the Second Hampden District; chief pathologist at Springfield Hospital, Wesson Memorial Hospital, and Wesson Maternity Hospital; consulting pathologist at the Holyoke (Mass.) Hospital and the Cooley Dickinson Hospital in Northampton; died Nov. 21, aged 75.

Kennedy, Paul Bernard, Hamden, Conn.; Bellevue Hospital Medical College, New York City, 1896; died in Shelton Nov. 25, aged 86.

Ketchum, Philip Vial, Palo Alto, Calif.; Fort Wayne (Ind.) College of Medicine, 1902; served as health officer of Laramie County and Cheyenne, Wyo.; died in the Veterans Administration Hospital, San Francisco, Nov. 24, aged 86.

Kionka, Paul B. Ⓜ Melrose Park, Ill.; Bennett Medical College, Chicago, 1893; died in the Westlake Hospital Nov. 9, aged 88.

Klepetar, Minna-Marie, Delhi, N. Y.; Deutsche Universität Medizinische Fakultät, Prague, Czechoslovakia, 1939; died in the Memorial Hospital, New York City, Nov. 8, aged 45.

Knaggs, Charles Warren Ⓜ Detroit; Detroit College of Medicine, 1903; died Nov. 21, aged 82.

Knowlton, Charles Colby Ⓜ Ellsworth, Maine; Harvard Medical School, Boston, 1911; past-president of the Hancock County Medical Society; served as a member of the state board of medical examiners; died in Bangor Nov. 23, aged 73.

Kuhn, Jerald Nelson Ⓜ Springville, N. Y.; University of Buffalo School of Medicine, 1941; interned at the Buffalo General Hospital; certified by the National Board of Medical Examiners; on the staffs of the Chaffee Hospital in Springville and the Buffalo General Hospital, where he died Nov. 24, aged 42.

Laughbaum, Thurman Ray Ⓜ Gainesville, Fla.; Ohio State University College of Medicine, Columbus, 1910; veteran of World War I; served in the U. S. Public Health Service during World War II; formerly health officer of Geary County, Kan., Marquette, Mich., Lake City, Mich., Madison County, Ohio, and Crawford County, Ohio; died Nov. 29, aged 75.

Lee, Harry Eugene, Houston, Texas; Meharry Medical College, Nashville, Tenn., 1902; associated with St. Elizabeth and Houston Negro hospitals; a member of the city board of health; died Nov. 17, aged 77.

Leggett, Clarence Dorsey Ⓜ Chillicothe, Ohio; Starling Medical College, Columbus, 1902; county coroner; died Nov. 16, aged 82.

Lehmacher, Frank Ⓜ Lakewood, N. J.; Columbia University College of Physicians and Surgeons, New York City, 1902; associated with the Paul Kimball Hospital, where he died Nov. 20, aged 81.

Lewis, David Hughes Ⓜ Spokane, Wash.; St. Louis University School of Medicine, 1907; past-president of the Spokane County Medical Society; fellow of the American College of Surgeons; died Nov. 20, aged 79.

Loar, Peter Andrew Ⓜ Silverton, Ore.; Kentucky School of Medicine, Louisville, 1903; past-president of the Marion Polk Counties Medical Society; for many years city health officer; long-time member of the Silverton Planning Commission; on the staff of the Silverton Hospital, where he died Nov. 18, aged 80.

McCutcheon, Thomas O'Donnell Ⓜ Upper Darby, Pa.; Medico-Chirurgical College of Philadelphia, 1909; on the staffs of the Thomas M. Fitzgerald Mercy Hospital, Darby, and the Delaware County Hospital, Drexel Hill; died Nov. 21, aged 80.

Major, Ralph Joseph Ⓜ Momence, Ill.; Loyola University School of Medicine, Chicago, 1933; interned at St. Anne's Hospital in Chicago; died Nov. 20, aged 51.

Maturi, Vincenzo E. Ⓜ Bayonne, N. J.; Universita di Napoli Facolta di Medicina e Chirurgia, Italy, 1922; member of the American Academy of General Practice; president of the medical staff of the Greenville Hospital in Jersey City, and on the staff of Bayonne Hospital; died Nov. 7, aged 61.

Michels, Julius Ⓜ Detroit; Rheinische Friedrich-Wilhelms-Universität Medizinische Fakultät, Bonn, Prussia, Germany, 1924; died Oct. 20, aged 64.

Noehren, Alfred Henry Ⓜ Buffalo, N. Y.; Columbia University College of Physicians and Surgeons, New York City, 1905; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; past-president of the Buffalo Surgical Society and the Buffalo Academy of Medicine; served as treasurer of the Erie County Medical Society; consultant, Edward J. Meyer Memorial Hospital; medical director and consultant at the Deaconess Hospital, where he served as a member of the board of managers and where he died Nov. 14, aged 80.

Olson, Chester Jerome Ⓜ Belle Plaine, Minn.; University of Minnesota Medical School, Minneapolis, 1925; member of the American Academy of General Practice; lieutenant commander, U. S. Navy, during World War II; died in St. Mary's Hospital, Rochester, Oct. 20, aged 64.

Platz, Charles H., Fort Collins, Colo.; The Hahnemann Medical College and Hospital, Chicago, 1903; formerly practiced in Columbus, Neb., Torrington and Casper, Wyo.; past-president of the Wyoming State Medical Society, Rocky Mountain Pediatric Society, and the Larimer County (Colo.) Medical Society; on the staff of the Larimer County Hospital; died Oct. 9, aged 88.

Rafle, Philip J., Riverhead, N. Y.; University of Buffalo School of Medicine, 1926; interned at the Children's Hospital of Buffalo; specialist certified by the American Board of Preventive Medicine;

Suffolk County health commissioner and former deputy health commissioner in Cattaraugus County; at one time regional health director for New York City; first vice-president of the Suffolk Medical Society; director of the North Fork Chapter of the American Red Cross; a director of the Suffolk Tuberculosis and Public Health Association, Suffolk County Cancer Committee, Suffolk County Chapter of the National Foundation for Infantile Paralysis, and Suffolk County Council of Social Agencies, chairman of the New York State Conference of City, County and District Health Officers; member of the New York State Medical Society Committee on Public Medical Care; fellow of the American Public Health Association, New York State Academy of Preventive Medicine, and the American College of Preventive Medicine; died Oct. 13, aged 58.

Ritter, James William Ⓜ Milwaukee; Marquette University School of Medicine, Milwaukee, 1946; member of the American Academy of General Practice; on the staffs of St. Joseph and St. Michael's hospitals; died Nov. 17, aged 38.

Robertson, John Hourne Ⓜ Endicott, N. Y.; Albany (N. Y.) Medical College, 1917; veteran of World War I; on the staff of the Ideal Hospital; died in the Wilson Memorial Hospital, Binghamton, Nov. 17, aged 66.

Rodlie, Olaf Erling, Huntingdon, Pa.; Kongelige Frederiks Universitet Medisinske Fakultet, Oslo, Norway, 1894; formerly practiced in Albert Lea, Minn.; died Nov. 23, aged 91.

Rutkauskas, *Anthony Kazis,* Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906; veteran of the Spanish-American War; died Sept. 29, aged 84.

Sage, Thomas Ⓜ Detroit; Detroit College of Medicine, 1931; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; associated with the Jennings Memorial Hospital, where he died Nov. 22, aged 58.

Edward Lewis Turner, M.D.
1900-1960

Turner, Edward Lewis Ⓜ Glenview, Ill.; born in Alton, Ill., Aug. 9, 1900; University of Pennsylvania School of Medicine, Philadelphia, 1928; interned at the University of Chicago Clinics; served a residency at Billings Hospital, Chicago; in February, 1959, named director of the A. M. A. Division of Scientific Activities, after serving as Secretary of the Council on Medical Education and Hospitals, which staff he joined in 1953; certified by the National Board of Medical Examiners; specialist certified by the American Board of Internal Medicine; for a time practiced in Bradford, Pa.; in 1945, appointed first dean of the University of Washington School of Medicine, Seattle, which he helped organize; from 1938 to 1944 president of the Meharry Medical College, Nashville, Tenn., where he served as professor and head of the department of medicine, and which he continued to serve as a trustee; at one time associated with the American University of Beirut, Syria, as head of the department of physiology, head of the department of medicine, and later as acting dean of the Medical School; past-president of the Tennessee State Anatomical Board, Tennessee State Basic Science Board, of which he was also past-vice-president; associate trustee of the University of Pennsylvania; director of the National Internship Matching Program; consultant, education and training division, Office of the Surgeon General, U. S. Army; consultant in tropical medicine to the Veterans Administration; served on the planning committee of the Second World Conference on Medical Education; fellow of the American College of Physicians; member of the Society for Experimental Biology and Medicine, Association of American Physicians, Central Society for Clinical Research, North Pacific Society of Internal Medicine, Washington State

Hospital Planning Council, Association of American Medical Colleges, of which he was vice-president in 1950-1951 and member of the executive council 1950-1953, Alpha Omega Alpha, Omicron Kappa Upsilon, and Sigma Xi; in 1955 his portrait was presented to the University of Washington at which time the Edward L. Turner Scholarship and Loan Fund for medical students was established; contributed many articles to professional journals; died in St. Francis Hospital, Evanston, Feb. 4, aged 59.

Upham, John Howell Janeway Ⓜ Columbus, Ohio; born in Trenton, N. J., Aug. 12, 1871; University of Pennsylvania School of Medicine, Philadelphia, 1894; interned at the Johns Hopkins Hospital, Baltimore; specialist certified by the American Board of Internal Medicine; served as President of the American Medical Association 1937-1938; member of the A. M. A. Judicial Council in 1922, and the Board of Trustees, 1923-1935, serving as chairman of the board from 1933 to 1935; dean of the faculty of the College of Medicine, Ohio State University, Columbus, 1927-1941, having been appointed professor of medicine in 1914; took postgraduate work at Prague, Leipzig, and Berlin, Germany; from 1902 to 1908 associate professor of medicine in Starling (Ohio) Medical College and in 1908 became professor of medicine and clinical medicine; represented the Federation of State Boards of Medical Examiners in the United States on the National Board of Medical Examiners; served on the State Medical Board of Ohio; secretary of the Ohio State Medical Association 1907-1913; formerly editor of the *Ohio State Medical Journal;* president of the state association 1914-1915, and at one time chairman of its public policy and legislation committee; in 1919 president of the Columbus Academy of Medicine; past-president of the Ohio Hospital Association; past-chairman of the Planned Parenthood Federation of America, Inc.; delivered the Emerling Lecture of the Pittsburgh Academy of Medicine in November, 1931; died Jan. 29, aged 88.

John Howell Janeway Upham, M.D.
1871-1960

Weaber, Thomas Hewitt Sr. Ⓜ Allentown, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1905; past-president of the Lehigh County Medical Society; past-vice-president of the Medical Society of the State of Pennsylvania, which in 1957 awarded him a plaque in recognition of his service of fifty years as a general practitioner in the community; for six years served on the school board; first medical examiner in the public schools in Allentown; for several terms on the Allentown Recreation Commission; chief emeritus of contagious disease section of the Allentown Hospital, where he died Oct. 31, aged 76.

FOREIGN LETTERS

AUSTRIA

Noise.—At a meeting of the Society of Physicians in Vienna on Nov. 27, F. Schwetz stated that modern man is surrounded at all times by sound. If man differentiates between sound (pleasant or neutral) and noise (unpleasant) the question arises: "What is this difference based on?" To answer this question the speaker subdivided the various sound intensities into subjective grades of noise, using Lehmann's scale. Grade 1 includes 0 to 69 phons. Only the emotional state of the person determines whether he is disturbed by noise at this level, but noise of grade 2, which includes 70 to 89 phons, causes vegetative disturbances and pathological vascular reactions. Noise of grade 3, which starts at 90 phons, leads to organic lesions in the inner ear. Workers in noisy factories are exposed to the greatest risk of such damage. In Vienna and its suburbs there are about 95 such plants. A team consisting of an engineer, an industrial hygienist, and an otologist has been formed to suggest means of improving conditions in these plants. At present it has examined more than 500 workmen exposed to excessive noise.

BRAZIL

Helminthiasis.—D. F. do Amaral of São Paulo (*Brasil-med.*, vol. 73, Aug., 1959) studied the action of dithiazanine iodide on several species of parasitic worms. The drug cured 89 to 100% of patients who were infected with Strongyloides stercoralis. It eradicated the parasites in all patients infected with Enterobius vermicularis. The percentages of cures in patients with Trichuris trichiura was 78 and 87. Ascaris lumbricoides infections responded better to hexylresorcinol and piperazine derivatives than to the new drug. Dithiazanine was not effective against Schistosoma mansoni. Dithiazanine was effective in only about 40% of patients with Hymenolepis nana. Side-effects of the drug included nausea, vomiting, diarrhea, and abdominal cramps that varied in intensity and were present in practically all patients at the beginning of treatments. Administration of chlorpromazine before the ingestion of dithiazanine ameliorated these effects.

Neoplastic Cells in the Blood.—Drs. Torres and Paulino of Rio de Janeiro studied a series of 52 patients with carcinoma (*Rev. brasil. cir.* 38:1, 1959). Venous blood was withdrawn from the tumor at the time of operation. The authors always chose the widest veins. When possible the blood was centrifuged, but if it was scanty direct smears were made. The centrifuged specimens contained a higher percentage of malignant cells. In all cases smears were also made of blood from the cut surface of the tumor to facilitate recognition of the malignant cells. Of the 52 patients 14 (26.9%) showed malignant cells in the veins. The authors concluded that the dissemination of malignant tumors through the venous blood is much more prevalent than was thought, in some patients being more rapid and more severe, than through the lymphatics. Thus, it is necessary to emphasize the importance of handling the tumors as little as possible during operation, since they should be subjected to minimal trauma. Furthermore the veins should be tied as promptly as possible.

FRANCE

Rheumatic Fever.—At a meeting of the Medical Society of the Hospitals of Paris, J. Chevallier presented a comparative study on various treatments for rheumatic fever in 497 children. The drugs used were salicylates, hormones (ACTH, cortisone, hydrocortisone, and delta cortisone), and phenylbutazone. Only 183 of the children did not have clinically perceptible abnormality of the heart before the treatment. Among the patients in whom no cardiac involvement was detected during auscultation at the beginning of the treatment, the speaker observed in 25 the appearance of a slight systolic apical murmur in the first two weeks in which they had the disease. This occurred with the same frequency with all groups, regardless of the way in which the patients were treated. The murmur persisted in half the patients until the end of the attack of rheumatism and usually disappeared within the next six months. Generally, if a child was free from cardiac symptoms at the onset of the disease he had a 90% chance of remaining clinically free from them until the end of the disease, regardless of the method of treatment.

On the other hand, in 30 to 50% of 34 patients who at the onset of the disease had either a systolic or a diastolic mitral defect and were given phenylbutazone and in 31 with the same cardiac disturbances who were given delta cortisone, the same signs of improvement were heard on auscultation. A cure without valvular sequelas was observed in

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

25% of the patients. Patients with severe cardiac disease and those with pericarditis were given hormones. Of the 497 children 4 died. This represented a tenfold decline in the death rate since the advent of hormone therapy. The sedimentation rate returned to normal within two weeks of hormonal treatment, within five weeks of salicylate treatment, and somewhat more slowly with phenylbutazone. The latter treatment was generally discontinued after four or five weeks.

Fibremia decreased more rapidly in patients treated with hormones than in those treated with the other drugs. The leukocyte count decreased below 8,000 within three weeks with the treatment of either salicylates or phenylbutazone, but with hormonal treatment the count increased in the first eight days of treatment. This often necessitated its interruption because of the risk of a complicating infection. The sudden interruption of hormone treatment and its replacement of salicylates caused within 24 hours an abrupt fall in the leukocyte count, which fell from 20,000 to 10,000 per cubic millimeter in some patients.

The author studied the post-therapeutic rebound, which usually took place after four to six weeks of treatment. Almost the only reaction was the increase in the sedimentation rate, which amounted to 30 mm. in the first hour and occurred one or two weeks after cessation of treatment, and it returned spontaneously to normal within two or three weeks. This reaction was seen after the treatment with hormones in 67% of the patients and after treatment with salicylates in 50% of the patients, but it rarely occurred after phenylbutazone therapy. The latter drug caused a slower and more regular fall in the sedimentation rate without the rebound phenomenon. The author concluded that delta cortisone was the treatment of choice for attacks of rheumatic fever, but the dosage used varied from hospital to hospital. An increase in the dosage above a certain quantity, which is different for each patient, did not bring about a more rapid fall in the sedimentation rate.

Electrical Injuries.—R. C. François (*Encyclopédia médico-chirurgicale,* 1959) stated that in patients with injuries from electricity, resuscitation should be started within the first few minutes after the accident without waiting for the transfer of the patient to a specialized center. In 15 patients in whom resuscitation was successful it was started in less than 10 minutes in 7, within 10 to 19 minutes in 3, within 20 to 59 minutes in 4, and after 90 minutes in 1. Ventricular fibrillation represented the greatest danger, but it might be corrected by electrical or pharmacodynamic defibrillation with barium or potassium chloride. The resuscitation of persons who had injuries caused by high-voltage current required special attention. They did not always faint initially. Careful watching was necessary because shock, intracranial hypertension, and anuria might appear any time within the next 48 hours. Anuria was produced by the liberation of myohemoglobin from the affected tissues. The patient should be given carbonated water to drink, since myohemoglobin is less toxic in an alkaline medium.

ISRAEL

Genital Listeriosis.—M. Rabinovitz and co-workers (*Harefuah* 57:277, 1959) examined 33 women who had had repeated abortions. In 24 of these the causative organism was found to be Listeria monocytogenes. In three of these the micro-organisms were isolated during pregnancy and the abortion occurred in the second trimester. In seven the Listeria were isolated in the first trimester of pregnancy. These patients were treated with penicillin and sulfamethoxypyridazine, and abortion was prevented. In 14 the micro-organisms were isolated when the patient was not pregnant.

Interstitial Myocarditis in Children.—An outbreak of primary acute interstitial myocarditis in infant in the Haifa district, observed early in 1957, wa reviewed by W. Falk and co-workers (*Harefuah* 57:149, 1959). The epidemic involved 57 children between the ages of 6 and 18 months. About 2 sporadic cases had been observed in 1955 and 1956 Fifty of the 57 children died. Roentgenograms revealed a general cardiac enlargement, progressing from slight dilation to extreme globular enlargement. Pulmonary congestion and pleural effusion were observed in almost every child. Electrocardiographic tracings showed normal conduction mechanism despite severe myocardial damage. The main characteristics were sinus tachycardia, low-voltage complex, frequent peaked P waves of high amplitude, deviation of the right axis, and alterations in the S-T segment and T waves. Autopsies, performed on 49 children, confirmed the diagnosis o primary myocarditis. In spite of the negative outcome of virological studies a viral agent was believed to be responsible for the disease.

NORWAY

Tetrabenazine.—Tetrabenazine, a benzoquinolizine derivative, has a reserpine-like action. In animals i produces sedation without hypnosis, potentiate ether anesthesia, and has a relatively low toxicity In clinical experiments it has proved especially effective against psychotic symptoms such as delusions and hallucinations without causing undesirable side-effects. Odd Lingjaorde (*Nord. med* 52:1576-1578 [Oct. 29] 1959) gave tetrabenazine in maximal daily doses of 100 mg. to 25 hospitalized schizophrenics. Sixteen of them had first received reserpine and nine were given reserpine afterwards. In both groups there was improvement in about half of the patients during tetrabenazine treatment. Side-effects were transient. Some of these were probably due to the sudden withdrawal of reserpine. The author concluded that tetrabenazine was probably better than reserpine in the treatment of hospitalized schizophrenics.

SWEDEN

Atomic Radiation on Mice.—The Institute of Zoological Radiation Genetics has been opened at the Karolinska Institute in Stockholm. Most of what is known about radiologic genetics is derived from experiments with fruit flies. At the new institute experiments are made on mice, as reactions in these animals are more easily comparable to reactions in human beings. In the laboratory, chromosomes are loaded with inheritable changes through radiation of every new generation of mice. The testes of the mice are exposed to 275 r. A person living in Sweden at 30 years of age is estimated to have received 2 r. After the first radiation of the animals not one of their 400 offspring had any serious defects, but the litters of radiated animals were smaller than those of unradiated control mice.

Plasma Volume.—Simultaneous determinations of the plasma volume with high-molecular-weight dextran and with Evans blue on 60 normal subjects and on 69 patients was reported by Lennart Jacobsson (*Acta Soc. med. upsal.* 64:1-24, 1959). Two separate dextran preparations were used. The plasma volumes obtained with one were higher and with one were lower than those obtained with the Evans blue method. The presence of dextran-reacting antibodies in plasma did not seem to influence the determinations. There were some difficulties in the determination of the concentration of Evans blue in plasma which were easily avoided when the dextran method was used. Hemolysis and lipemia might introduce errors into the Evans blue method. In patients with highly icteric serums the Evans blue injected was less completely bound to the albumin, and the rapid loss of free stain caused an erroneously high estimation of plasma volume. In addition there might be a variation in the absorption of the same amount of stain in the plasma of different subjects. The occurrence of varying amounts of impurities of the different preparations also influenced the results, as the disappearance rate of the impurities from plasma was very rapid.

In some disease states the use of dextran of high molecular weight is to be preferred to the use of Evans blue for the determination of the plasma volume. Conditions in which increased permeability is present cause an overestimation of the plasma volume as determined with Evans blue or iodine-tagged albumin. This error can be reduced by the use of a dextran preparation of high molecular weight where even the lowest molecular weights can be kept at a level above that of albumin. On the intravenous injection of dextran untoward reactions appeared in a few patients. They were mild or moderate and probably did not influence the plasma volume determination. Discoloration of the skin never appears when dextran is used instead of Evans blue. Dextran is only transitorily deposited in various organs and tissues and disappears without leaving a trace. The coefficients of variation were of the same magnitude for the dextran and the Evans blue methods in the normal subjects, and from this point of view the two methods were equally accurate.

Effects of Barometric Pressures on Respiration.—C. M. Hesser and B. Holmgren (*Acta physiol. scandinav.* 47:28-43, 1959) studied the effects of raised barometric pressures on the respiratory systems of eight healthy patients at rest in a compression chamber. They used 100% O_2, and 5% O_2 in N_2 at various ambient pressures. With increasing ambient pressure (up to 4 G) respiration became progressively slower and deeper. The reduction in respiratory rate and the increase in tidal volume were caused mainly by the increase in gas density and hence in breathing resistance and to a lesser extent by the concomitant increase in oxygen tension.

When ambient pressure was increased from 1 to 4 G the respiratory minute volume gradually decreased and then increased slightly. The gradual decrease was caused partly by the increasing breathing resistance and partly by the removal of chemoreflex drives due to the concomitant increase in oxygen tension. The reduction in minute volume at 4 G was probably due to the increase breathing resistance. At 4 G the calculated effective alveolar ventilation was somewhat increased. The authors concluded that this increase occurred because the stimulating effect of high oxygen tension on respiration was greater than the suppressing effect on respiration of increased breathing resistance. Functional dead space volume showed no consistent difference in any of the conditions studied, which confirmed the conclusion of other investigators that the volume of the dead space is independent of the inspired oxygen tension and the density of the inhaled gas.

At 4 G the dead space/tidal volume ration was decreased as a consequence of an unaltered dead space volume and an increased tidal volume. Raising the ambient pressure to 4 G caused no consistent change in the respiratory exchange ratio, which suggested that no important interference with the pulmonary gas exchange occurred, even when the density of the inhaled gases was increased four times. Expiratory reserve volume showed no significant change in any of the conditions studied, which suggested that the long volume at the midrespiratory level increased with raising ambient pressure, since the tidal volume then increased. Nitrogen at pressures of 3 or 4 G exerted little, if any, depressant action on respiration, no matter whether the oxygen tension was normal or elevated.

Estriol.—N. E. Borglin (*Acta obst. et gynec. scandinav.* 38:157-171, 1959) studied the effect of estriol on a series of 75 patients, mostly postmenopausal. The drug increased the vascularization of vaginal mucosa. The cervical mucus increased in quantity, became watery, and resembled that associated with ovulation. It crystallized with a typical palm leaf pattern. In patients with uterine prolapse the descent of the uterus and vaginal walls decreased, and if the dose of estriol was too large, the prolapse was likely to retract so much as to cause technical difficulties at operation. There was a slight change in the cytological findings with an increased number of vaginal cornified cells and a decreased number of basal cells. The effect suggested a moderate estrogenic effect.

Histologically, there was a thickening of the epithelium with distinctly outlined cell layers, an increased number of basal cells, and rapid regeneration. The submucosa became edematous and loose with increased vascularity, while the cervical canal proliferated and became wider. The glandular epithelium appeared to be in a state of secretory activity. The endometrium increased in thickness. The basal layers showed an increased number of glands which in the functional layer were cystic and dilated, while the stroma was loose. No endometrial bleeding was observed. In many patients the endometrium responded only slightly. The effect of estriol on repair operation, the postoperative course, and such complications as bleeding, wound disruption, urinary tract infections, and retention of urine were comparable with the effect of other estrogens. The author concluded that estriol was an excellent drug for treating postmenopausal prolapse.

Effect of Relaxin on the Duration of Labor.—Engström and Wiqvist (*Acta obst. et gynec. scandinav.* 38:172-180, 1959) studied a series of 130 multiparas at or near term in whom labor was induced by oxytocin injection, the most frequent indication being Rh-sensitization. The fetus with the head presenting was alive at the time of commencement of the oxytocin drip in all cases. Thirty patients were given relaxin and oxytocin, and 100 received oxytocin alone. The latter were used as controls. The latent phase (the interval between starting the oxytocin drip and the commencement of regular uterine contractions) was significantly prolonged in the group treated with relaxin and oxytocin. In this group the duration of the average latent phase was 4.93 hours; it was 3.01 hours in the controls.

The first stage of labor was defined as the interval between the commencement of regular contractions and full dilatation of the cervix, while the second stage was defined as the interval between full dilatation of the cervix and delivery. In the present series there was no significant difference between the two groups in the duration of the first and second stages of labor, but in the group treated with relaxin and oxytocin a slight tendency for relaxin to shorten the second stage was observed. In the control group a smaller quantity of oxytocin solution was required. The authors concluded that when true labor pains had started relaxin might facilitate dilatation of the cervix, which would result in acceleration of the first and second stage.

Surgical Treatment of Focal Epilepsy.—Modern surgical treatment of focal epilepsy offers special anesthesiological problems because during the operations it is necessary to establish contact with the patients and to record the electrical activity of the cortex. Regional anesthesia during the craniotomy was customarily used. While this method did not interfere with the electrical activity of the cortex and permitted communication with a fully conscious patient, the patient had to lie in a fixed and rather uncomfortable position during a long and tedious operation. Furthermore it was difficult and sometimes impossible to prevent pain. While certain of these disadvantages might be overcome by premedication with morphine and barbiturates, this involved the risk of depressing respiration and more specifically of interference with the electrical activity of the cortex.

D. H. Ingvar and co-workers (*Acta anaesth. scandinav.* 3:111-121, 1959) used regional anesthesia in combination with nitrous oxide administered with 25% oxygen through an endotracheal tube in 23 operations for focal epilepsy. Through a perforated double cuff on the tube a local anesthetic for the trachea could be administered repeatedly. The administration of nitrous oxide was interrupted for periods of 10 to 30 minutes in the operations during which electrocorticography was carried out. During such periods it was possible to establish contact with the patient. The periods of wakefulness were well tolerated, and no side-effects due to the presence of the endotracheal tube were observed. This procedure was not used when speech functions had to be tested specifically during the operations. A comparison with a group of 26 patients operated on under regional anesthesia showed only that the nitrous oxide procedure did not interfere with, or tend to hide, epileptogenic abnormalities in the electrocorticogram.

Clinical Trial of Secergan.—Dr. J. Tomenius (Svenska läkartidningen, Nov. 6, 1959) treated a series of 94 patients, (43 with peptic ulcer, 42 with gastritis, and 9 with functional disturbances of the intestinal tract). Of these, 48 were given secergan, a phenothiazin derivative with marked anticholinergic action, and 46 were given a placebo. Complete freedom from symptoms was achieved by 66% of those given secergan and by only 30% of those given the placebo. This difference was most marked among the patients with peptic ulcer, the figures being 70 and 30% respectively, but those with gastritis also showed the relative inferiority of the placebo. The reason that the placebo was impotent is that the patients lived in an ambulatory condition and were sheltered from the influence of psychotherapy which is always operative in a hospital atmosphere. In this test the element of confusion introduced by dieting, sedatives, and hypnotics was avoided. No disagreeable side-effects, such as dryness of the mouth and throat, eye symptoms, or disturbances of micturition, followed the administration of secergan.

A Quick Test of Hearing.—In 1951 in the northern part of Sweden, 32,885 schoolchildren underwent the old clinical test of listening to the spoken word at a certain distance. Among them 218, or 0.7%, were found to have defective hearing, yet routine tests throughout Sweden in recent years with an audiometer have shown with remarkable uniformity that 3.3% of the schoolchildren suffer from defects of hearing serious enough to interfere with learning. The discovery of these defects usually came as a surprise to pupil, teacher, and parents. As Dr. L. Holmgren (Svenska läkartidningen, Nov. 6, 1959) pointed out, the general practitioner cannot be expected to equip himself with the type of audiometer used by the Audiological Laboratory of the Karolinska Hospital for various tests, but a handy substitute for this instrument is the Quick-Check Audiometer which has been in use in Sweden during the past year and which is supplied with a miniature electric battery capable of lasting a year when used economically (only a few seconds for each test).

Azacon in Psychiatry.—At a mental hospital in Malmö, 140 men suffering from schizophrenia or other psychiatric ailments were treated with azacon, whose chemical structure somewhat resembles that of chlorpromazine but whose clinical effect differs from that of this drug. Commenting on these cases Drs. Uddenberg and Lundgren (Svenska läkartidningen, Nov. 20, 1959) stated that 73 of the patients suffered from latent schizophrenia, 21 from active schizophrenia, and 11 from psychoses due to injuries to the brain. The rest had other psychiatric ailments. Azacon was usually given by mouth, the dosage ranging from 40 mg. thrice daily to 80 mg. three or four times daily. When the patients did not respond to the larger doses, the drug was abandoned in favor of chlorpromazine. In Germany, however, good results were obtained with up to 1 Gm. of azacon daily. Though azacon may not deserve to replace chlorpromazine altogether, it possesses the advantage of not provoking the parkinsonism or lassitude to which the recipients of chlorpromazine are liable. Some time before a patient is discharged it is well to start giving him azacon rather than chlorpromazine in order to facilitate his adaptation to life outside the hospital. The postchlorpromazine lack of initiative can thus be avoided. The side-effects of azacon are on the whole harmless and transient.

UNITED KINGDOM

Speeding by Doctors.—A physician successfully appealed against sentence on his conviction for speeding while on an emergency call. He was fined 12 dollars by Lancashire magistrates and had his driving license endorsed after pleading guilty of speeding at 48 miles an hour in an area restricted to 30 miles. The magistrates did not consider that the circumstances constituted a special reason for not recording a conviction. Under the law speeding may be permitted under exceptional circumstances, for example by the police or by fire engines. The Appeals Committee, however, reversed the magistrates' decision and held that speeding by the doctor called to an urgent case did in fact constitute an exceptional circumstance. Legal commentators pointed out that this decision must not be taken as a carte blanche for speeding by doctors when called to an emergency. Each case must be decided on its own merits. The degree of urgency of the call must be balanced against the degree of danger to the public in speeding. As one commentator pointed out, there is no benefit in killing a pedestrian to save a patient.

Antibiotics for Bronchitis.—Chronic bronchitis is a major cause of industrial invalidism and results in the annual loss of 22 million male working days. Murdoch and colleagues studied the therapeutic effects of the continuous treatment of bronchitics during the winter months with oxytetracycline and tetracycline (*Brit. M. J.* 2:1277, 1959). A series of 98 bronchitics were given capsules containing either a mixture of 167 mg. of tetracycline and 83 mg. of oleandomycin or 250 mg. of oxytetracycline while the control patients had capsules containing an inert powder. Four capsules a day were given. Progress was assessed from bacteriological examination of sputum and nasal swabs and from clinical response, the patient being graded as improved, unchanged, or worse. The results of the trial clearly showed that men with chronic bronchitis benefited from continuous daily treatment during the winter months with one of the tetracyclines. This was found to be particularly the case in elderly bronchitics with advanced disease. The absence of recurrent winter invalidism and consequent loss of time from work was a noticeable advantage of continuous antibiotic therapy, as shown by the comparison of days lost by treated as compared with untreated patients. It was concluded that the best time to start treatment is in the autumn. The occurrence of an acute exacerbation of bronchitis in those patients receiving the inert capsules led to their withdrawal from the trial.

The degree of purulence of the sputum was found to be a useful guide to the efficacy of antibiotic treatment, since there was good correlation between it, the clinical state of the patient, and the presence of Hemophilus influenzae and Diplococcus pneumoniae in the sputum. The dose of antibiotic was adjusted so that the sputum remained mucoid. This was about 250 mg. four times a day. Looseness of the stools was troublesome in about 33% of the patients, but in none was it associated with a significant change in the intestinal flora. Additional confirmation of the role of H. influenzae in chronic bronchitis was the demonstration of high antibody titers in the serums of patients who regularly harbored this organism in their sputums. It was suggested that H. influenzae has the invasive properties which lead to the inflammatory destruction of bronchopulmonary tissue demonstrable in chronic bronchitis. Bronchoscopic aspirates yielded H. influenzae in most patients with purulent sputum.

Some of the strains of Staphylococcus aureus isolated during and after treatment were resistant to the antibiotics used, but this did not constitute a real danger. Gross disturbance of normal surface flora of the respiratory and intestinal tracts was not observed. It was found practicable to treat the patients on an outpatient or domiciliary basis, which had the advantage of lower cost than hospital treatment. To avoid the dangers of superinfection with antibiotic-resistant and often highly virulent microorganisms it was recommended that if exacerbations should arise the patient is better treated at home rather than in the hospital. One serious consideration was the cost of such antibiotic treatment, which is about 180 dollars for six months, or 7 dollars a week, if the patient is treated by his own doctor. This compares favorably with the cost of hospitalization, which is nearly 62 dollars a week in a good teaching hospital, and the additional charge on the state for sickness benefit and the financial loss to industry.

Shortage of Surgeons.—A London consultant pointed out in the *Daily Telegraph* of Dec. 18 that on Dec. 2 at a large London hospital of good reputation, there were four applicants for a post of house surgeon to three surgeons with general and special surgical interests. The applicants were one Englishwoman and three men from Ghana, Jordan, and Siam respectively. There was no Englisl male applicant. The difficulty experienced in recen years, at a small hospital some 10 miles from London, of getting a caucasoid male house surgeon c resident surgical officer is now becoming mor common in London. Such a lack of homebred, c even Canadian, South African, or New Zealanc applicants is a new phenomenon and augurs ill fc the future. The reason for this situation may b sought in the cavalier treatment of medical deputations to the Ministry of Health and in the psychological and financial pin-pricks and gener atmosphere of denigration to which the medic profession has of late been subjected. In medicin there is often a family tradition, but physicians n longer urge their sons or daughters to enter th profession.

Midwives Dying Out.—Maternity work in Gre Britain is largely in the hands of midwives. A mi wife, after four years' training, can now start $1,610 a year (31 dollars a week). A district mi wife who has the responsibility of life and death her hands and is on duty 144 hours a week inclu ing Christmas and other holidays, must often li in the most austere circumstances. Income ta superannuation, and insurance all must be paid o of her inadequate salary. This niggardly mann of treating the women who bring 750,000 babies year into the world is having the inevitable resu Fewer persons are becoming midwives.

In 1959 only 16,445 midwives were registered practicing, or nearly 500 less than in 1958. Th number of district midwives was 7,790, or near 200 less than in 1958. About 3,000 midwives qual fied last year, but 3,500 left Britain. Kenya ar New Guinea offered posts at 62 dollars a wee Vancouver offered 347 dollars a month for a 40-hou week; and Newfoundland offered 53 dollars week plus full maintenance. In Britain there are 1,0 closed beds in hospitals due to the shortage midwives.

Television Neck.—A condition known as "televisio neck" may follow watching television from a cha of the wrong height, according to the *Lancet* Dec. 26. The author warns that to sit endless watching TV brings a risk of illness, includin heart trouble, but the hazard is small and shoul not be exaggerated. Simple syncope is not unusu when surgical procedures are shown, and tr angina pectoris may be provoked by some pr grams. Prolonged immobility in an awkward po ture entails a risk of venous thrombosis. On medical writer recommends that viewers move fro their chairs at least once an hour. Flickering of the set has been known to initiate a fit in a susceptible epileptic.

CORRESPONDENCE

STATISTICS AND TOBACCO

To the Editor:—I am shocked by your editorial on smoking and lung cancer. Could you define the kind of evidence which you would accept as showing a relationship between cigarette smoking and ung cancer?

DAVID D. RUTSTEIN, M.D.
Department of Preventive Medicine
Harvard University Medical School
Boston 15.

See the following communication.—ED.

To the Editor: In THE JOURNAL, Nov. 28, 1959, page 1829, appeared a statement[1] of the surgeon general of the U. S. Public Health Service, Dr. L. E. Burney, on smoking and lung cancer, which has been widely interpreted in the editorial press as an authoritative pronouncement of the Public Health Service and as a definitive opinion on the scientific issues involved in that controversial subject. I beg to present some reasons for doubting each of these evaluations.

In general, the article is characterized by an imprecision of language and thought that renders inaccurate almost every important point it deals with. In particular, it contains some frank errors of omission and commission which are misleading with regard to the basic questions at issue. On page 1830 it is stated, "Berkson . . . noted that the data of Hammond and Horn and of Doll and Hill point not only to an association between smoking and lung cancer but also to a wide variety of diseases never presumed to have the same etiology as cancer." The reference is to a communication[2] that was written shortly after the publication of the two reports with which it deals and before any statistics from the large prospective study being conducted by Dorn for the Public Health Service were issued. I did not merely note the presence of an "association" of smoking with a wide variety of diseases. I emphasized that only about 14% of the "excess deaths" reflected in the higher death rate of smokers compared to nonsmokers were due to lung cancer, while 86% were due to causes other than lung cancer. Fairly soon after the publication of some statistics from Dorn's study, I presented an analysis[3] disclosing similar findings in Dorn's data, which showed only 12.7% of the excess deaths to be due to lung cancer, 9% due to other cancer, and 78.3% due to other causes.

Burney's article deals meagerly with Dorn's reports and mentions only some findings with respect to lung cancer. Taken together with the omission of reference to my second report, this presentation can easily mislead the reader to believe that my quoted observations, referring to the studies of Doll and Hill and of Hammond and Horn, do not apply to the study of Dorn, when, in fact, the opposite is true. Similarly, his summary of the report of Hammond and Horn mentions only some data on the relation of smoking to deaths from lung cancer in face of the fact that the report[4] itself says, "A total of 7,316 deaths occurred among regular cigarette smokers, an excess of 2,665. . . . Coronary disease accounted for 51.2 per cent. . . , lung cancer . . . for 13.5 per cent, and cancer of other sites likewise 13.5 per cent. . . . The most important finding of this study was the high degree of association between cigarette smoking and total death rate."

The finding of associations of smoking with all classes of disease, not only or even chiefly with lung cancer, is of central importance for an interpretation of the biological significance, if any, of these statistical studies,[5] and Burney's presentation, which obscures them, could leave an impression of misrepresentation.

On page 1833 an argument for smoking as a cause of lung cancer is advanced on the basis of the lower mortality from lung cancer among women, which appears to have made a strong favorable impression on some editors.[6] Here it is stated that "nonsmoking women have about the same lung cancer death rate as nonsmoking men," which, almost certainly, is not true. The death rate for men is greater than that for women, not only for cancer of the lung but for cancer of almost every organ that is comparable in the two sexes and for virtually every noncancerous disease also.[7] The higher general mortality of the male than the female is characteristic of the entire animal kingdom; it is usually related by biologists[8] to the presence of two X chromosomes in the cell of the female and only one in the male, not to smoking. One would not know, reading this portion of the surgeon general's statement, that a special study[9] devoted to the sex ratios of mortality from lung cancer had been published, with conclusions different from his, for it is not mentioned in his text or references.

On page 1834 one reads, "In the study of Leuchtenberger and co-workers . . . mice were exposed to cigarette smoke and examined after varying periods, the longest being 200 days. In most animals the bronchial epithelium showed inflammation and simple and atypical basal cell hyperplasia. Passey . . . stated, however, 'Our failure during the past five years [recorded in previous publications] to induce lung tumours in mice, rats, and hamsters by exposure to strong concentrations of cigarette smoke is a striking negative result.' " The impression one gets from these passages is that the results of Leuchtenberger and associates contradict, or at least mitigate, those of Passey, who obtained negative results in attempts to produce lung cancer experimentally by exposure to smoking.

The report of Leuchtenberger and co-workers[10] referred to in the passage is an early, preliminary one. A later report of this work was given by Leuchtenberger and others at the International Cancer Congress in London, in July, 1958. The summary of this report[11] reads as follows.

> 1. There is a development of a bronchitis associated with a gradual change of the normal resting epithelium to an inflammatory, proliferating, and dysplastic one ("carcinoma in situ," multifocal). *No invasive carcinoma.*
> 2. When exposure to cigarette smoke is stopped for over 3 months, the normal appearance of the bronchi suggest reversibility of bronchitis and dysplasia.
> 3. The cytochemical alterations in the bronchial epithelium also show a gradual development. . . . The cytochemical alterations are also reversible when exposure to cigarette smoke is stopped.

This later report of Leuchtenberger and others is, in content and in tone, virtually the same as Passey's, not in contrast to it.

An even less explicable lapse is Burney's failure to cite the experiments performed in the Public Health Service itself, in the laboratory of the pathologist, Dr. H. L. Stewart, in which administration of cigarette smoke to mice failed to produce lung cancer.[12]

So it is found that, in these parts of his text, Burney refers to a report of Leuchtenberger and co-workers in an equivocal way with respect to the experimental production of lung cancer by smoking, while omitting reference to a later report by the same author and others which is emphatically clear as to the failure to produce such cancers, and he omits entirely any reference to experiments with similar negative results performed in the U. S. Public Health Service laboratories.

The article is presented as a statement of the Public Health Service. When I read this I was surprised, for the following reasons. Several weeks before the article appeared, I had presented a paper[13] related to the present subject at a biometrics seminar of the Public Health Service in Bethesda, Md. The paper was technical and intended to demonstrate mathematically that some statistical methods which had been used in the analysis of the prospective studies of smoking and lung cancer were unsound, with consequent misinterpretation of the data in these studies. The talk was well attended, and I assume the audience contained a fairly large proportion of the biometricians in the Public Health Service. I did not sense, during my talk or during the discussion that followed, any disagreement with the tenor of my remarks. I recall clearly that when I said, "We should not be engaging in fine semantic efforts to demonstrate that the extremely complicated statistical evidence proves the validity of the theory that initiated these studies. Instead, we should set up investigations in large variety to find out what they mean," there was spontaneous applause, from what seemed to be the entire audience.

I spent considerable time with Dr. Dorn and with some veteran experimental workers of the Public Health Service and have corresponded with others. I cannot speak didactically of their views, but I can say that they seemed in general agreement with mine, as regards the tentative character of the evidence. Surely, I had the impression that Dorn believes that much more work in pharmacology, pathology, and other associated sciences must be done before anything definite can be said with regard to the explanation of the statistical findings. Certainly, the word "cause" does not appear in any of his writings on the subject, and he has recently expressed himself elaborately on the complexities of interpreting statistical results for their etiological significance.[14] In these circumstances, and recalling the insufficiency of Burney's reporting of Dorn's statistics, I cannot believe that Dorn reviewed or edited the statement of the surgeon general before its publication, nor can I believe that Stewart did considering that his own work was not cited, leaving aside other inaccuracies that I cannot believe him to have approved. Dr. Dorn is chief of biometrics of the National Institutes of Health and the director of its main statistical study on smoking and lung cancer. Dr. Stewart is chief of pathology and a renowned worker in the field of experimental cancer. If neither of these scientists of the Public Health Service previewed the surgeon general's article before publication, not to speak of the failure to consult many other experts in related fields on its staff, how can this article be properly designated a statement of the Public Health Service?

There is an aspect of deficiency of the surgeon general's statement that is of even more serious import than those just discussed. If the Public Health Service believes that tobacco smoke contains chemical carcinogens which cause lung cancer, then the first task of its responsible scientists is to isolate these substances in "pure culture" and to identify their chemical structure. This is the first step required by Koch's postulates for demonstration of a causative agent of a disease. It is furthermore the first step to be taken in order to use the discovery for amelioration of the disease. Since Pasteur, the isolation of a specific cause of a disease has been followed immediately by experiments to produce an immunizing agent. The Public Health Service has had appropriated for its use in a single year about 700 million dollars; about 350 million dollars has been for the National Institutes of Health, in cluding 85 million dollars for the National Cancer Institute, with about 20 million dollars allocated specifically for research in chemotherapy. How much of these considerable funds has been spent or allocated for carrying out the first steps to be taken to realize the discovery of an important cause of lung cancer? So far as I can learn, none at all. So far as I know, the only experiment on smoking in relation to lung cancer published from the Public Health Service is the negative experiment [10] that I cited above, and no work of this nature is in progress now.

As I have repeatedly pointed out, the prospective studies show more excess deaths among the smokers from other causes than from lung cancer, and these other causes are distributed among all classes of disease. If the statistical results are not spurious but reflect some real biological effect, this points to a generalized, not a local, effect. I have presented a plan [15] for an experimental epidemiologic study to explore this lead. Why has not the Public Health Service set up this experiment, or some modification of it?

Sir Ronald Fisher, who has been critical of the analysis of the English data on smoking and lung cancer,[16] early remarked, "The question seems to be a serious one; when is serious investigation going to begin?" His question is timely even now.

ELI LILLY MEDICAL RESEARCH FELLOWSHIP (SOUTH AFRICA)

To the Editor:—The attention of medical practitioners registered in South Africa, who may at present be in the United States, is drawn to the fact that applications may now be submitted for the 1960 award of the Eli Lilly Medical Research Fellowship. The fellowship is given for the purpose of medical research and is not intended for postgraduate clinical study. The net value of the fellowship is $300 per month for 12 months, plus return traveling expenses to the point of study in the United States of America. Further details can be obtained from me. The closing date for applications is April 30, 1960.

H. A. Shapiro, M.D.
Honorary Chairman: Selection Committee
Eli Lilly Medical Research Fellowship
P. O. Box 1010
Johannesburg, Union of South Africa

FAT CONTENT OF SEMEN

To the Editor:—In my busy practice, I find myself several weeks behind in reading The Journal, and it was only last night that I had an opportunity to review the Aug. 1, 1959, issue. I would like to know where the scientist who prepared the answer to the question on page 1756 of this issue obtained the caloric values for fat given.

D. S.
New York City.

I regret to state that the person who prepared the reply has been given another assignment and is not available for comment.—Ed.

MEDICAL FILM REVIEWS

The Buffering of Carbon Dioxide During Hypercapnia: 16 mm., color, sound, showing time 24 minutes. Prepared by Gabriel G. Nahas, M.D., Washington, D. C. Produced in 1959 by and procurable on loan from Research Films Section, MAVD, Walter Reed Army Institute of Research, Washington 12, D. C.

The data presented in this film are preliminary and are documentations of unconfirmed research investigation. It shows the use of a tris buffer (THAM) in treatment of hypercapnia of apneic respiration. It thoroughly describes the cardiovascular and metabolic responses of two dogs to hypercapnia, one untreated and one treated with THAM. This is followed by a short graphic summary of the results. Many small items are not fully explained and could be confusing to medical students. Because of inappropriate film cutting, pentothal appears to be injected rapidly, resulting in instantaneous anesthesia. The cannula placed in the cisterna magna was allowed to drip for some time and was never connected to the pressure transducer. The mechanism of action of the compound could have been more completely described. Dangerous side-effects from its use are not mentioned. Technically, the film is well done: however, the production is amateurish in spots. The subject should be of interest to medical students, graduate students in physiology and pharmacology, anesthesiologists, and those interested in acid-base balance as affected by respiratory disease.

A Pharmacologic Approach to the Study of the Mind: 16 mm., black and white, sound, showing time 33 minutes. Produced in 1959 by Sherman Dryer Productions, New York, for and procurable on loan from Lakeside Laboratories, Inc., 1707 E. North Ave., Milwaukee 1.

This is a series of excerpts from a conference held at the Langley Porter Clinic on the topic indicated by the film title. Ralph Gerard introduces the speakers and serves as general interlocutor. The conference was opened by Alec Simon, who commendably recommended an attitude of "healthy skepticism." Various comments on LSD and mescaline were then made by James Dille, Sidney Cohen, and others, and by Leo Abood on his studies of the various piperadyl benzylates. These reports revealed wide disagreement as to whether (*a*) these "psychotomimetic" drugs cause "true" or "merely toxic" psychoses, or whether (*b*) they are of diagnostic or therapeutic value. The conference continued with a note by J. Kinross-Wright on the favorable effects of beta-phenylisopropyl hydrazine hydrochloride (Catron) on depressive reactions, and with predictions by J. Pomeranz, Nathan Kline, and others to the effect that such monoamino-oxidase inhibitors may largely replace electroshock therapy in certain patients. Dr. Gerard closed the conference on the same healthy note with which it opened: a healthy skepticism. More pictures of patients would have been an improvement. The kinescope recording used in the film is poor. The film may be of interest to a specialized audience of psychiatrists or psychopharmacologists. It is not suitable for viewing by general medical audiences.

NEW FILMS ADDED TO A. M. A. MOTION PICTURE LIBRARY

Open Fractures: 16 mm., color, sound, showing time 24 minutes. Produced in 1959 by Churchill-Wexler Film Productions for the Veterans Administration. Prepared by William A. Larmon, M.D., Chicago. Procurable on purchase from Churchill-Wexler Film Productions, 801 N. Seward St., Los Angeles 38, or on loan (service charge $2) from Motion Picture Library, American Medical Association, 535 N. Dearborn St., Chicago 10.

The basic principles underlying the treatment of open fractures are illustrated in this film. It shows a typical patient, with a fractured tibia, being given emergency treatment at the site of an automobile accident. Further treatment in the emergency room of the hospital, surgery, and postoperative care are shown in detail. Definitive surgery is demonstrated in the operating room in two different patients, one treated by the open method and one by primary closure. It is an exceptional film on open fractures. The content is excellent and scientifically accurate. The photography, narration, and general organization are good. Animation is used extensively to demonstrate procedures, both in concept and practice. The film has broad application and is recommended to general practitioners and the medical profession as a group. It can also be used to advantage by interns and residents and is highly recommended to medical students, especially in the junior and senior years.

Mouth to Mouth Resuscitation for Respiratory Emergencies: 16 mm., color, sound, showing time 18 minutes. Prepared in 1958 by Archer S. Gordon, M.D., Los Angeles. Procurable on loan (service charge $2) from Motion Picture Library, American Medical Association, 535 N. Dearborn St., Chicago 10.

This film details the physiological requirements for effective artificial respiration and outlines the experimental and [illegible] of the development of [illegible]. The subject of resuscitation is concisely covered and the film demonstrates the mouth-to-mouth method and three manipulative methods which have been effective. A complete review of this film appeared in THE JOURNAL, Oct. 31, 1959, page 1253.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Chlorothiazide as a Diuretic Agent in the Treatment of Congestive Cardiac Insufficiency. A. Dräyer B., P. Blanco H. and S. Henriquez E. Arch. Inst. cardiol. Mexico 29:533-545 (Sept.-Oct.) 1959 (In Spanish) [Mexico, D. F.].

Twenty-eight patients with congestive cardiac insufficiency of varied etiology were treated with chlorothiazide for an average period of one month in the cardiology department of the University Hospital of Caracas, Venezuela. The patients' ages ranged from 12 to 65 years. The daily dose of chlorothiazide was 1 Gm. for each patient (500 mg. every 12 hours). The treatment was preceded by an observation period of one week, during which the patients were kept on a low-salt diet with a constant sodium and potassium content. The cardiac insufficiency was considered to be compensated when the venous pressure, both at rest and after hepatic compression, was within the normal limits.

The results of the therapy were excellent (decrease of the venous pressure to normal values, total disappearance of hepatic congestion and of the clinical manifestations of cardiac insufficiency) in 15 patients (53.75%). In 10 patients (35.75%) the results were good, with the venous pressure remaining somewhat higher than the normal values. In only 3 patients was the treatment a failure. In one of these patients the administration of prednisone (30 mg. on the first day, followed by a daily dose of 20 mg. during 23 days) produced an increase in the urinary output and in the excretion of sodium and potassium, resulting in compensation of the cardiac insufficiency. The most constant and important electrolytic change was the increase in the excretion of potassium, without the amount consumed in the daily diet being exceeded. In spite of this ratio, however, hypopotassemia was observed in 19 patients (67.8%). The patients who were followed up and were kept under chlorothiazide therapy continued to be free from edema and symptoms of cardiac insufficiency. Unfavorable reactions were few and in no case caused interruption of the treatment or decrease in the dosage. The authors believe that chlorothiazide is as effective as the mercurial diuretic agents, is better tolerated, and is easier to administer. Its effects are more uniform; its side-effects are fewer and less marked.

Congenital Defects in Bilirubin Metabolism as Seen in the Adult. L. Schiff and B. H. Billing. Gastroenterology 37:595-602 (Nov.) 1959 [Baltimore].

The authors differentiate 3 types of congenital defects in bilirubin metabolism in adults. First, they discuss constitutional hepatic dysfunction (Gilbert's disease), which is characterized by elevation only of free bilirubin level in the serum, either as a result of deficiency of a hepatic conjugating enzyme or, more probably, as a result of impaired hepatocellular uptake of bilirubin from the plasma. In the second type of disorder, chronic idiopathic jaundice (Dubin-Johnson syndrome), the levels of free bilirubin and conjugated bilirubin are elevated in the serum, and pigment is found in the liver. The third type of disorder, which has been described only recently, is chronic familial nonhemolytic jaundice with conjugated bilirubin in the serum. This syndrome is characterized by the presence of conjugated as well as free bilirubin in the plasma, the values for which may fluctuate. Bile pigments can be detected in the urine, provided that the level of conjugated pigments in the plasma is sufficiently high. Diminished conjugation by the hepatic cells, as well as a defect in excretion, is assumed. These disorders are of interest and importance to both clinician and investigator. To the clinician, recognition avoids treatment for the wrong diagnosis of hepatitis or biliary tract disease and provides a basis for reassurance and a favorable prognosis. To the investigator, the mechanisms of these disorders are challenging, and their study should advance knowledge of liver function and liver disease.

Tuberculosis in Women. C. Palenzona. Minerva med. 50:3271-3274 (Oct. 17) 1959 (In Italian) [Turin, Italy].

The author made a study of the incidence of tuberculosis among women as compared with that among men. The study is based on observations by the author and by other workers in Italy, France,

---

The place of publication of the periodical appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by persons in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1956 to date for English language and 1958 to date for foreign language journals. No photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

and Switzerland. In the past the incidence of tuberculosis was highest in the puberal age, and at that time more girls than youths died of it. Presently, in civilized countries, the primary infection has gradually tended to take place later in life. This fact explains the current higher incidence of tuberculosis among men than among women of all ages except in adolescence. At the present, the mortality rate among those dying of extrapulmonary tuberculosis in Italy is approximately equal in both sexes, but the mortality rate of all varieties of tuberculosis is more than double among men. Women are more cooperative than men in participating in treatment of the disease, which circumstance accounts for a slightly better prognosis in women than in men.

Pregnancy, labor, and puerperium are no longer adverse conditions for a woman with tuberculosis, provided that the patient is hospitalized. The author reports that during the past 4 years 7 pregnant women with active tuberculosis, who were hospitalized at the clinic with which he is associated, delivered healthy infants. Six of the women were discharged as cured within a few months after the delivery, but one patient died 3 years after childbirth. The author performs a pneumoperitoneum if cavities in a woman after delivery remain refractory to chemotherapy. Vocational readjustment, if necessary after completion of the treatment for tuberculosis, is easier for a woman than a man because, by tradition, women in Italy rarely perform heavy manual work.

Congenital Deficiency of Proconvertin: A Clinical and Laboratory Report. S. P. Miller. Blood **14**:1322-1338 (Dec.) 1959 [New York].

The authors report a case of congenital deficiency of proconvertin (factor VII) in a 2-year-old Hopi Indian boy, who had a moderately severe hemorrhagic tendency since birth, but essentially normal intrinsic coagulation despite the absence of detectable levels of proconvertin by the methods currently available. In 10 cases collected from the literature, a deficiency of the identical factor missing in this patient appeared to be present. Thus, the case of this patient is the 11th case of "pure" proconvertin deficiency and the second reported in the American literature. The patient's plasma reacted normally to plasma thromboplastin generated in the normal incubation mixture, and normal plasma reacted normally to the patient's thromboplastin. The patient's own thromboplastin gave a normal reaction when subtested against the patient's plasma. Abnormal results were obtained when the patient's coagulation was studied in the presence of tissue extracts. The one-stage assays utilizing brain thromboplastin were markedly abnormal in test systems sensitive to a deficiency of proconvertin. These included the one-stage prothrombin time of Quick and the proconvertin assay. An accompanying mild deficiency of prothrombin was suggested by the results of some tests.

The concept that the role of proconvertin in hemostasis is primarily as a co-thromboplastin is supported by the clinical and laboratory studies carried out in this patient. The differentiation of "pure" proconvertin deficiency from other cases of deficiencies of "serum factors," particularly deficiency of the Stuart factor, has been discussed. A total of 65 cases, labeled deficiency of serum prothrombin conversion accelerator (SPCA), proconvertin, factor VII, or Stuart-Prower factor, have been collected from the literature and reviewed.

Hyperbilirubinemia Due to an Alternate Path of Bilirubin Production. L. G. Israels, H. J. Suderman and S. E. Ritzmann. Am. J. Med. **27**:693-702 (Nov.) 1959 [New York].

The authors report on 4 cases of hyperbilirubinemia, which occurred in 2 families from southern Manitoba, Canada. Three patients (2 brothers and a sister) belonged to the same family and had developed jaundice for the first time at puberty. Their father also had had an episode of jaundice at the age of 12 years. One brother and the sister underwent splenectomy. In both patients the spleen weighed approximately 350 Gm.; histologically, the pulp and sinuses contained prominent endothelial cells. Biopsy specimens of the liver, taken from both patients, showed a heavy infiltration, a brown pigment occurring as granules of irregular shape and size in the hepatic parenchymal cells, and being primarily concentrated in the periphery. The fourth patient was a 40-year-old woman, with no direct kinship to the other 3 patients. This woman had been asymptomatic until the age of 18, when she was found to be jaundiced and anemic. At 31 she developed splenomegaly. One year later she was hospitalized, and a diagnosis of spherocytic anemia was established. The removed spleen was congested, and the endothelial cells lining the sinuses were prominent. There was no excessive deposition of iron. The hemoglobin level rose, the serum bilirubin level fell, and the jaundice was less marked after the operation. The patient still tired easily, although otherwise she was well.

The patients reported on were free from antecedent hepatitis, and all exhibited some features of congenital spherocytosis, such as jaundice, splenomegaly, spherocytes in the peripheral blood, and an increased osmotic fragility on incubation. There were also some marked differences from congenital spherocytosis. Autohemolysis and mechanical fragility were normal. After the splenectomy, the survival of radioactive sodium chromate (Cr^{51}) was extended to normal, the serum bilirubin value was reduced, and the urine urobilinogen dropped to one-half of the preoperative level, while an appreciable hyperbilirubinemia persisted, together with reticulosis and normoblastic marrow. The total urobilinogen output remained high in the presence of a normal Cr^{51} red blood cell survival time. The authors suggest that the excess bilirubin had its source in the marrow erythrocytes or their precursors, either by their destruction or by their synhesis of bilirubin directly from heme or its tetrapyrrole antecedents. The occurrence of 3 cases of hyperbilirubinemia with the same features in the ame family indicates that it is a familial disease, probably representing an autosomal recessive characteristic.

A Familial Study in Idiopathic Hemochromatosis. T. H. Bothwell, I. Cohen and others. Am. J. Med. 27:730-738 (Nov.) 1959 [New York].

Fifty-two immediate relatives (parents, siblings, and children) of 6 patients with idiopathic hemochromatosis were observed. The diagnosis of hemochromatosis was confirmed at autopsy in 5 patients and by liver biopsy in 1. Each of the relatives was examined clinically, and determination of fasting serum iron was performed on all subjects, except 5 young children. Liver biopsies were performed on those showing persistently raised serum iron evels. Of 19 siblings investigated, 3 manifested the clinical symptoms of the disease, and 5 showed varying degrees of iron excess on liver biopsy. Six of the siblings with negative findings were under the age of 20 years and might exhibit manifestations at a later period. In one family the mother showed a persistently raised serum iron level, in spite of a normal liver biopsy. In another the father had hepatomegaly and a raised serum iron level. In 3 children of 2 patients there was evidence of the iron metabolism defect.

The results support the concept that idiopathic hemochromatosis is a familial disorder in which the absorption of excessive amounts of iron from the intestines eventually leads to a massive accumulation of iron within the body. The disease is probably the result of an autosomal genetic defect of incomplete penetrance and/or variable expressivity, which is transmitted as a Mendelian dominant trait. The practical value of familial studies in idiopathic hemochromatosis is stressed, since affected persons can thus be detected and treated during the preclinical phase of the disease.

Vitamin B_{12} and Folic Acid Metabolism in Hookworm-Infected Patients. M. Layrisse, N. Blumenfeld, I. Dugarte and M. Roche. Blood 14:1269-1279 (Dec.) 1959 [New York].

The authors report on 21 patients with severe anemia and heavy hookworm infection (groups A and B), who were hospitalized in the medical wards of Hospital Vargas and Hospital Universitario in Caracas, Venezuela, also on 5 patients with light hookworm infection who were hospitalized for symptoms distinct from anemia (group C), and on 5 noninfected patients with various degrees of iron-deficiency anemia (group D), in whom studies on folic acid and vitamin B_{12} metabolism were carried out as a part of the study of the antianemic factors in these patients. In a group of healthy laboratory workers (group E), only serum vitamin B_{12} and folic acid tests were performed. The patients of groups A and B harboring severe hookworm infection showed significantly low serum levels of vitamin B_{12}, as compared with the healthy laboratory workers. Eight of the 21 patients studied showed values of serum vitamin B_{12} below 100 micromicrograms per 100 cc. Twelve of 13 patients with severe hookworm infection showed impairment of the pteroylglutamic acid intestinal absorption; however, none of them showed megaloblastic proliferation in the bone marrow. They all recovered with iron therapy alone. The 5 patients with light hookworm infection and the 5 patients with iron-deficiency anemia but without hookworm infection did not show significant differences in the results of the serum vitamin B_{12} and folic acid tests from those of the healthy persons studied. Although the reported data on vitamin B_{12} and folic acid metabolism are not sufficient to permit a firm conclusion, they nevertheless suggest that, in addition to the blood loss associated with hookworm infection, some other nutritional factors may be involved in patients with this infection.

NEUROLOGY & PSYCHIATRY

Familial Periodic Paralysis: Report of a Case Resistant to Dextrose and Insulin Provocation. R. F. Chen. A. M. A. Arch. Neurol. 1:475-484 (Nov.) 1959 [Chicago].

Familial periodic paralysis is a disease of unknown etiology characterized by recurrent acute attacks of weakness associated with a fall in serum potassium levels. The author cites literature reports to the effect that acute and/or repeated attacks of paralysis may be brought on by a variety of factors, and that familial periodic paralysis must be distinguished from a variety of acute paralytic syndromes, among which are both hypopotassemic and hyperpotassemic conditions. He presents the detailed history of a 14-year-old boy who presented many characteristic features of familial periodic paralysis. He had a familial history; his mother had attacks of weakness in her arms, and 2 uncles on his mother's side had similar paralytic episodes. The symptoms began at puberty, were severer in cold weather, and were absent during the summer; they occurred frequently at night, were precipitated by heavy meals, could be counteracted by active and passive motion, were accompanied by low potassium levels, and could be terminated by the administration of potassium chloride. Although attacks developed at home with great frequency, this patient exhibited resistance to the provocative effects of the administration of dextrose and insulin in the hospital. It is inferred that this resistance was due to a relatively low sodium intake while on a routine hospital diet. The patient experienced attacks despite potassium prophylaxis, but became asymptomatic after receiving dietary admonitions.

There is evidence that the fall in serum potassium level brings about paralysis by altering muscle-membrane potential. Clinical, histological, and metabolic studies suggest fluid and electrolyte changes, mediated by a hormonal abnormality. Greater frequency of attacks at night supports this view. Periodic paralysis associated with hyperthyroidism seems closely related to classic familial periodic paralysis, and there may be some interplay between thyroid, adrenal, and muscle in this disease.

GYNECOLOGY & OBSTETRICS

Effects of Preoperative Irradiation on Adenocarcinoma of the Uterus. H. E. Schmitz, C. J. Smith and W. C. Fetherston. Am. J. Obst. & Gynec. 78:1048-1059 (Nov.) 1959 [St. Louis].

For many years the authors have combined preoperative irradiation with surgery in the treatment of endometrial carcinoma. They do not seek a middle-of-the-road compromise between a surgical and a nonsurgical approach. They feel that preoperative irradiation is an adjunct to the therapy. They review observations on 280 patients with uterine cancer admitted to the gynecologic service of the Mercy Hospital institute of radiation therapy, Chicago, regardless of extent of disease or previous therapy. For comparative purposes, the cases are divided into a series prior to 1946, which has been previously reported, and a series from 1946 to 1953, inclusive, in which more precise and refined techniques were used. In 71 of the patients treated between 1946 and 1953, the preferred techniques were employed, which begin with the insertion of the Y radium applicator on 3 separate occasions for a dose of 2,000 mg.-hr. per application, or a total dose of intracavitary radiation of 6,000 mg.-hr. These applications are at weekly intervals, with the administration on intervening days of deep x-ray therapy through 2 ports, anterior and posterior, with a 1,000 kv. machine and adequate stripping in the midline to protect bladder and rectum from overdosage. After the third intracavitary application, daily external irradiation is continued until a total dose at the midpelvis of 3,500 to 4,000 r is administered. The actual dose to the endometrial surface from the intracavitary radiation is of the order of 20,000 to 40,000 gamma r.

From 6 to 8 weeks after the completion of this program, abdominal hysterectomy, with a generous cuff of vagina and bilateral salpingo-oophorectomy, is performed. Of the 71 patients treated with preoperative radiation followed by operation, 55 showed no tumor in the surgical specimen—a sterilization rate of 77.4%. Similar studies on specimens in the group prior to 1946 showed a sterilization rate of 57%. The authors believe that, even if tumor persists, the irradiation retards the spread of tumor cells. They suggest that irradiation provides a twofold antineoplastic effect, namely, the specific metabolic inhibiting effect through nucleus injury, and what might be termed a general deterrent effect by raising the host resistance either through a general somatic response to a profound physiological injury or by the increase in body resistance mechanisms through the stimulation of radiant energy.

The over-all 5-year survival rate in the 280 patients was 57.2%. In the first series of 138 patients treated between 1934 and 1945, the 5-year survival was 47.4%. The second group of 142 patients treated from 1946 to 1953, inclusive, showed an over-all 5-year survival rate of 67%. This improvement of 20% in the over-all figures can be attributed to improvements in all phases of therapy, inasmuch as it includes patients treated by all modalities. Of the 142 patients in the present series, 106 were operated on, giving an operability rate of 74.7%. This operability rate is rising among the authors' more recent cases, as well as among other reported series. In the aforementioned group of 71 patients the 5-year survival rate was 81.6%, and further analysis shows that it is possible to salvage 96% of patients so treated.

The Detection and Treatment of Carcinoma of the Uterine Cervix at Its Preinvasive Stage: Observations on 58 Patients. Presse méd. 67:1923-1925 (Nov. 7) 1959 (In French) [Paris].

This study is based on observations made on 58 patients with preinvasive carcinoma of the uterine cervix, who were treated between 1950 and 1958 at the St. Louis, Bichat, and Port Royal hospitals in Paris. The patients' ages ranged from 24 to 63 years, the average age being 38.7 years. None of the patients exhibited any symptoms. In 47 of the 58 patients the cervical lesions were clinically considered benign, and in 11 patients the lesions were clinically suggestive of carcinoma. Study of the patients in this series shows that pregnancy seems to play a certain role in the etiology of carcinoma; only 2 patients were nulliparous, whereas 45 were multiparous. The method of choice for the detection of preinvasive carcinoma is considered to be the Papanicolaou smear technique, to be followed, when indicated, by conization of the cervix and histological examination of the tissue removed. Thirteen of the 58 patients were found to have residual carcinoma in the surgical specimens after conization. The incidence of residual lesions after conization seems to depend on the coning technique itself rather than on the glandular invasion and surface extension or depth of the lesion. When all necessary histological criteria are present for the diagnosis of preinvasive carcinoma, the diagnosis as such must be made, whether or not the patient is pregnant.

Surgery is the treatment of choice for carcinoma of the cervix at its preinvasive stage. The safest procedure is a total hysterectomy, with or without preserving the adnexa. More conservative treatment consists of supravaginal cervical amputation or simply conization, which must be reserved for women who wish to keep their reproductive organs. These latter patients must be closely followed over a long period of time. As a rule, the patient is cured by excision of the lesion, and the consistency of these results should stimulate all efforts of early diagnosis of these lesions.

Two Cases of Supernumerary Ovary and One of Accessory Ovary, With an Analysis of Previously Reported Cases. L. R. Wharton. Am. J. Obst. & Gynec. 78:1101-1119 (Nov.) 1959 [St. Louis].

The author presents the histories of a woman with a supernumerary ovary who came under his observation recently, and of one woman with a supernumerary and of another with an accessory ovary from the records of the Johns Hopkins Hospital, Baltimore. He also reviewed the available records of previously reported cases. In practically all studies of this subject, since the first report by Grohe in 1864, the authors have attempted to classify these anomalies. There has been a general agreement on 3 basic principles: 1. The term "supernumerary ovary" includes those rare cases in which the third ovary is entirely separate from the normally placed ovary and apparently arises from a separate primordium or anlage. 2. The term "accessory ovary" includes those cases in which the excess ovarian tissue is situated near the normally placed ovary, may be connected with it, and seems to have been developed from it, possibly from tissue that was split from the embryonic ovary during its early development. 3. The supernumerary or accessory ovary must contain ovarian follicular tissue. Additional criteria have been added during recent years, but some of these were arbitrary and had no embryologic foundation.

In addition to the 2 cases of his own, the author found 2 other cases of supernumerary ovaries in the literature and 18 reports on accessory ovaries. The distinction between the two is at times uncertain, and there have been differences of opinion concerning classification. The author failed to find a single instance in which the correct diagnosis was even suspected before the operation. In most cases, the operator, after seeing the lesion, thought it was fibrous tissue or a lymph node. In a few cases, the structure was so small that it was concealed by adherent pathological masses. Hence, the only cases of accessory or supernumerary ovary that are ever recognized are those discovered at autopsy or in which disorders develop in the accessory or supernumerary ovaries, such as tumors or cystic changes. The exact incidence of this rare condition in otherwise normal women is impossible to determine.

The literature includes 26 reports by different authors, each recording one or more cases of pelvic or abdominal tumors in women who, in addition, had 2 ovaries. Since these tumors were of types that often arise from the ovary, these authors concluded that these tumors must have arisen from a third ovary, and have reported them as accessory or supernumerary ovaries. The pathological diagnoses of these various tumors included dermoid cyst, simple cyst, papillary cyst, multilocular cyst, cystadenoma, pseudomucinous cyst, chocolate cyst, granulosa-cell tumor or carcinoma, and myosarcoma. The literature contains 4 reports of women who continued to menstruate after a bilateral oophorectomy, and it also records 2 instances in which women conceived after a bilateral oophorectomy. The reports concerning the persistence of uterine function after bilateral oophorectomy are difficult to evaluate. The author is inclined to share the opinion of some that in most instances it was due to an incomplete removal of the ovaries, rather than the presence of supplementary or accessory ovaries.

Amniotic Fluid Embolism and Infection. R. G. Valenzuela, H. C. Soto and G. Z. Castagnini. Obst. y ginec. latino-am. 18:335-346 (July-Aug.) 1959 (In Spanish) [Buenos Aires].

The authors report 5 cases of amniotic fluid embolism which occurred among 37,000 deliveries observed on the maternity ward of San Francisco de Borja Hospital in Santiago de Chile from 1956 to 1958. In 2 patients fetal death had preceded labor; in 1 the fetus died soon after labor induction; these 3 patients died before completion of labor. In 2 patients the children were delivered live. In all 5 patients there were signs of amniotic fluid infection manifested by high temperature, chills, and foul odor of the fluid. Only one patient survived, a 35-year old primipara who entered the maternity ward in labor, with weak contractions. After a 48-hour-long uterine inertia, oxytocin was administered intramuscularly, which caused rather intense uterine contractions. The delivery was terminated by cesarean section. During the operation a marked infection was detected, its main sign being the foul odor of the amniotic fluid and of the fetus. The patient developed sudden and intense cyanosis and dyspnea, and excreted a frothy pinkish sputum. Collapse and hypotension with tachycardia occurred. Therapy with lanatoside C, morphine, and oxygen was instituted. A roentgenogram taken the following day showed extensive shadows over both pulmonary fields. At physical examination, a crepitation could be heard. The clinical picture gradually improved, and the roentgenographic image and the fibrinogen level became normal.

The authors believe that the 2 main factors in the causation of amniotic fluid embolism are uterine contractions of a tetanic type and infection. Pulmonary roentgenograms and determination of circulating fibrinogen are valuable aids in the diagnosis. As prophylactic measures, the authors recommend investigation and treatment of infection of the fetus, and advocate restriction and, in some cases, avoidance of oxytocics, especially by the intravenous route. As therapeutic measures, they advise intense oxygen therapy and the administration of opiates and/or artificial hibernation in order to minimize the vagal reflexes produced by pulmonary emboli.

Post-Partum Panhypopituitarism. B. J. Pascoe and A. E. McGuinness. M. J. Australia 2:635-640 (Oct. 31) 1959 [Sydney].

The 8 cases of postpartum panhypopituitarism presented were seen at Sydney Hospital during the last 4 years. The authors call attention to Sheehan's contributions to the understanding of the etiology, pathology, and clinical manifestations of this condition. The 8 cases are divided into 2 groups: (1) 6 cases in which the syndrome remained unrecognized for some years and (2) 2 cases in which the condition was recognized 2 months and 8 days, respectively, after the delivery causing onset of the syndrome.

Tabulations of the data on the first 6 women show that they ranged in age from 35 to 68 years, and that their symptoms had persisted for from 7 to 27 years. With minor variations, these 6 women had the characteristic clinical pattern emphasized by Sheehan, namely, the history of collapse at delivery, followed by absence of lactation and of menstruation; a gradual loss of pubic and axillary hair, pallor, and dryness of the skin; loss of energy, apathy, and mental slowing; disinclination to carry out minor household duties; and abnormal sensitivity to cold. The appearance may be typically myxedematous, or may be that of premature senility. These persons, as a group, are loath to seek medical advice, and if they do so, it is not uncommon for a diagnosis such as anemia or myxedema to be made, with subsequent poor response to therapy. Some patients are admitted to hospital in coma. Laboratory investigations reveal low basal metabolic rates and low urinary steroid levels. There may be anemia, achlorhydria, low blood sugar levels, and a flat dextrose tolerance curve. The corticotropin (ACTH) stimulation test may distinguish the primary hypoadrenalism of Addison's disease from the secondary form occurring in panhypopituitarism. Patients with panhypopituitarism show little or no response on the first or second day of ACTH infusion, but respond significantly by the third day. Thus, they may be distinguished from nonendocrine cases (which respond on the first day) and from cases of primary adrenal insufficiency, which never respond to ACTH stimulation. The history of recurrent pyelonephritis in 3 of the 6 cases may be significant. Mild hypertension was noted in 3 of the women, but this did not seem to be related to renal disease. Pigmentation of the hands, arms, and face was observed in one of the patients. Two patients experienced episodes of coma.

Of the 2 women in whom the panhypopituitarism was recognized early, one was 26 years old. The delivery of her first child had been complicated by toxemia, dystocia, forceps delivery, retained placenta, severe postpartum hemorrhage, and profound shock, requiring transfusion of 3 liters of blood. After recovery, she suffered puerperal infection with pyrexia and offensive lochia. On returning home, she was listless, weak, and apathetic. On the basis of a diagnosis of postpartum panhypopituitarism, she was given 12.5 mg. of cortisone 3 times a day, and 32 mg. of thyroid once a day. This produced great improvement. Six months later she was bright and active, but there was no return of menstruation or of pubic hair. The second patient, a 34-year-old woman, was delivered of a stillborn fetus, with subsequent severe hemorrhage and shock. She died 10 days later, and autopsy revealed complete necrosis of the anterior pituitary lobe. Observations on this series of cases show that the diagnosis of postpartum panhypopituitarism depends on familiarity with its common manifestations and on awareness of its possible occurrence, in varying degrees of severity, as a sequal to obstetric collapse.

Trophoblast in the Circulating Blood During Pregnancy. G. W. Douglas, L. Thomas, M. Carr and others. Am. J. Obst. & Gynec. 78:960-973 (Nov.) 1959 [St. Louis].

It has been established that trophoblast finds its way into the pulmonary circulation of women who die during pregnancy, particularly in circumstances involving convulsions and intrauterine manipulation; terminal events may be responsible for these trophoblastic embolisms. The growth of trophoblast away from villous attachments and its migration into the blood stream may also occur as a normal pattern of behavior, in the same manner as syncytiotrophoblast wanders among the interstices of uterine muscle. One consequence of such migration should be the appearance of trophoblast not only in the lungs but in the circulating blood during pregnancy.

In searching for trophoblast in the circulating blood, the authors employed a method similar to that employed by Moore in the search for cancer cells. They were able to demonstrate syncytiotrophoblast in the circulating blood of pregnant women from the 18th week of gestation to term. The demonstration of syncytiotrophoblast in circulating blood drawn from vessels draining the uterus, at various stages of gestation, makes it clear that the process of deportation may be regarded as a constant migration of this tissue into the blood stream during pregnancy. While the methods employed at the present do not permit an estimation in quantitative terms of the amount of tissue involved or of its relation to various complications of pregnancy, there is no doubt that this phenomenon is an accompaniment of normal pregnancy and not a result of death throes and intrauterine manipulation.

The migration of these cells into the blood stream may be of profound significance. In a broad sense, pregnancy plays the biological role of a homograft, since both placental and fetal tissues have a genetic derivation different from the tissues of the maternal host. The genetic and immunological requirements for successful homotransplantation of tissues are such that grafting between humans has generally been possible only in the case of monozygotic twins. It is clear that in pregnancy some fundamental means have been developed to escape the fate of the homograft, so that existence of the conceptus for the period of gestation becomes immunologically possible. Explanations for this apparent exception to homograft behavior are considered. It may be that the fetal tissue which lies in juxtaposition to maternal tissues, the syncytiotrophoblast, is so embryonal and devoid of antigenic capacity that it is not recognized by the maternal host as an intruder. Or, if the syncytiotrophoblast is recognized as foreign tissue, the mechanisms of rejection are held in abeyance by some intrinsic feature of pregnancy which allows a sort of immunological truce. Production or localization of cortisone or similar steroids by the placenta might also provide for this mechanism of tolerance. A third possibility is suggested by the work of Billingham, Brent, and Medawar, in which tolerance to homografts was induced in animals by the prior injection of the donor's cells. It is conceivable that a similar mechanism is present in human pregnancy, and that the migration of trophoblast into the blood stream throughout gestation is the means by which "tolerance" is achieved.

Abruptio Placentae and Rupture of the Marginal Sinus of the Placenta: Some Relationships. J. H. Ferguson and R. L. Hatton. Am. J. Obst. & Gynec. 78:947-959 (Nov.) 1959 [St. Louis].

The authors explain similarities and differences between abruptio placentae and rupture of the marginal sinus of the placenta on the basis of observations on women with these accidents observed over a 3½-year period at the University of Miami-Jackson Memorial Hospital, Miami, Fla. There were 113 cases of abruptio placentae and 130 cases of rupture of the marginal sinus. All 113 cases diagnosed as abruptio placentae showed changes on the maternal aspect of the placenta that were considered characteristic of this lesion. The placenta exhibited one or more of the following signs: a sizable clot attached to the maternal surface, a depression obviously caused by a clot, or unequivocal changes in the color and texture of the maternal surface. In all 130 cases of rupture of the marginal sinus the placentas satisfied the anatomic criteria for the diagnosis. An attendant at delivery noted that there was a clot at the margin of the placenta and that that clot was continuous with clotted blood in the marginal sinus. If examination of the placenta indicated that the clot had ever been between the maternal surface of the placenta and the uterus, the diagnosis of abruptio placentae was made. The diagnosis of placenta previa was eliminated by vaginal examination.

There were no great differences between the 2 forms of placental accidents with regard to vaginal bleeding or the delivery of premature infants. Vaginal bleeding was observed in 82% of the 113 women with abruptio placentae and in all of the 130 with rupture of the marginal sinus. Premature delivery occurred in 50% of the 111 single births to the women with abruptio placentae and in 46% of the women with rupture of the marginal sinus. In this last group the neonatal mortality rate was high; while 54 of 58 premature infants were born alive, 19 died during the neonatal period. The chief dissimilarity between abruptio placentae and rupture of the marginal sinus is in their danger to the mother and fetus. Abruptio placentae carries grave risks for both mother and fetus, while rupture of the marginal sinus poses less of a threat. It is understandable that true abruptio placentae, with its dissolution of the placenta-uterine union and its shock, should have a high stillbirth rate. Despite a readiness to perform cesarean section, the authors had a 55% stillbirth rate; fetal heart tones could not be heard on admission to the hosptial in 43% of these cases. The stillbirth rate among women with rupture of the marginal sinus was only 2%.

Because of differences in the symptoms of the 2 conditions, the authors were often able to differentiate them before delivery. Seventy-six per cent of the patients with abruptio placentae had one of its typical symptoms, and 32% had the complete triad of pain, hypertonicity, and tenderness of the uterus. These symptoms were rarely noted in cases of rupture of the marginal sinus, and then generally were milder. There were 2 characteristics that abruptio placentae and rupture of the marginal sinus frequently had in common, namely, a tendency for the lesions to occur at the dependent portions of the placenta and a tendency to low implantation. This anatomic similarity suggests that under certain conditions one syndrome may be a precursor of the other.

Spontaneous Rupture of the Liver in a Patient with Acute Toxemia of Pregnancy. D. Retikas and N. Karanouh. Ohio M. J. 55:1523-1525 (Nov.) 1959 [Columbus].

Spontaneous rupture of the liver is rare, only 15 cases having been reported. The 16th case, presented in this paper, was that of a 37-year-old woman, in the 32nd week of her 4th pregnancy, who was admitted to Mercy Hospital, Canton, Ohio, on Sept. 9, 1957, with complaints of headache, dizziness, nausea, and vomiting, associated with slight pain and tenderness of the epigastrium and the right upper quadrant. Her blood pressure was 230/120, and the pulse rate 92 per minute. The uterus was enlarged to the size of a 32-week gestation. The fundus was 3 fingers below the xiphoid process. The patient was admitted to the delivery room with a diagnosis of acute toxemia and possible chololithiasis. Half an hour later, she complained of pain in the epigastrium; the blood pressure dropped suddenly, and 15 minutes later it was unobtainable. The patient appeared to be in deep shock. The fetal heart rate was absent, but the contractions of the uterus became stronger and more frequent. With a diagnosis of abruptio placentae or internal hemorrhage from rupture of the uterus, cesarian section was performed, and a stillborn female infant was extracted.

The woman's abdominal cavity was filled with fresh blood. There was a large transverse laceration, about 6 cm. in length, on the anterior surface of the left lobe of the liver. The anterolateral surface of the right lobe was covered with a subcapsular hematoma. The laceration was packed and sutured. About 15 minutes after surgery, the blood pressure dropped again to zero. During the next five hours the patient was in shock. She died 10 hours after admission. Autopsy was performed, and the following causes of death were assumed: (1) acute focal necrosis of the liver with subcapsular hemorrhage and rupture of Glisson's capsule; (2) intraperitoneal hemorrhage with shock; (3) clinically acute toxemia of pregnancy.

Spontaneous hemorrhage of the liver may result from acute toxemia, but rupture of Glisson's capsule from massive hemorrhage is one of the rarest complications. The patient did not have any marked trauma or convulsion. However, the question of insignificant trauma during the transportation of the patient, as well as during palpation or examination, cannot be ruled out. Toxemic patients are notorious for their tendency to spontaneous hemorrhage, and besides the common hemorrhagic lesions of the liver and the high incidence of premature separation of the placenta, many suffer hemorrhage into the subarachnoid space, into the brain, into the rectus muscle, and into the retroperitoneum from the pancreas. The pathological physiology of eclampsia suggests the importance of fibrinogen depletion as the cause of these hemorrhagic phenomena. Patients in acute toxemia, with pain in the right upper quadrant and the epigastrium and with rapid development of shock, should suggest the possibility of rupture of the liver. The only hope for recovery lies in surgery. Measures for hemostasis are suture of the damaged portion of the liver; packing of the laceration with Oxycel, fat, muscle, or omentum; and electrocoagulation by cautery. In severe cases the mortality may reach 50% despite surgery.

PEDIATRICS

Symptomatic Neonatal Hypoglycemia Associated with Toxemia of Pregnancy. M. Cornblath, G. B. Odell and E. Y. Levin. J. Pediat. 55:545-562 (Nov.) 1959 [St. Louis].

This report describes 8 cases of spontaneous hypoglycemia, with signs beginning on the second or the third day of life in infants born to mothers with preeclampsia. Convulsions, apnea, tremor, and limpness in these infants were immediately alleviated after parenteral administration of dextrose, which sometimes had to be maintained for prolonged periods in order to keep the blood sugar at normal levels. The age at onset of these signs varied between 40 and 72 hours. Six of the 8 infants were considered premature, at least by weight (in 7 cases the length of pregnancy was 36½ weeks or longer). All had been fairly well until the onset of the first signs of hypoglycemia, which were listlessness and refusal of feeding after having taken milk well. These signs were followed by loss of muscle tonus and, after a variable period of time, by cyanosis, tremors, and convulsions. The blood sugar level at the time of the convulsions ranged between 1 and 24 mg. per cubic centimeter. In 5 infants the spinal fluid sugar ranged from 0 to 15 mg. per cubic centimeter. Various tolerance tests were performed in an attempt to elucidate the etiology of the hypoglycemia observed. These included administration of glucagon or epinephrine, as a test for available hepatic glycogen, and of casein or leucine, as a test for hypoglycemia precipitated by amino acids.

Five of the infants reported were well at the time of the follow-up study, made within 44 days to 11 months after birth. Two infants suffered permanent damage of the central nervous system, and one died at the age of 17 days. The occurrence of hypoglycemia in these 8 infants suggests that this condition plays a role in the high morbidity and mortality rates among children born to mothers with preeclampsia. The high rates may be due, in part, to the administration of drugs, such as barbiturates, morphine, and the hexamethonium compounds, to the mother, but for the most part the cause of the disease is unknown. Since hypoglycemia can be responsible for apnea, cyanosis, limpness, and convulsion in the newborn infant, it should be considered in the differential diagnosis in the offspring of toxemic women. The need for more careful observation of these infants in the nursery is apparent.

A Note on the Development of Gaucher Cells in a Newborn Infant. J. Bernstein and W. E. Shelden. J. Pediat. 55:577-581 (Nov.) 1959 [St. Louis].

This report describes the uncommon occurrence of signs and hematological abnormalities characteristic of Gaucher's disease in a newborn infant. Although the "storage" cells were cytologically atypical, this development provided an opportunity for observing the cellular changes in the earliest stages of the disease. The infant, a girl weighing 6 lb. 5½ oz. (2,876 Gm.) at birth, was born after a normal full-term pregnancy. The parents were apparently healthy, although the father later died of carcinoma of the pancreas. Of 2 other children, one was normal and the other, a 3-year-old, had suffered from chronic Gaucher's disease for 1½ years. Besides exhibiting signs of Mongolism and cutaneous purpura, the infant developed vomiting and diarrhea at 3 days of age. She was then transferred to the Children's Hospital of Michigan, in Detroit. The blood cell count per cubic millimeter was 6.5 million erythrocytes, 18,150 leukocytes (on admission to the hospital; 7,000, 4 days later), and 38,250 platelets (falling to 13,400). Despite negative stool cultures, the infant continued to suffer from diarrhea and episodes of cyanosis. Her condition progressively deteriorated, and she died after a severe cyanotic episode, at the age of 14 days.

At autopsy, large abnormal cells were found in the spleen, containing fibrillary cytoplasm which could be stained with the periodic acid-Schiff, Sudan black B, and Hale dialyzed iron procedures. Only the spleen was increased in size. The liver and bone marrow contained scattered, large, lightly Schiff-positive cells resembling those in the spleen. The only abnormality in the brain were nerve cell heterotopia in the white matter and cerebellar cortical disruption, of the type frequently found in Mongolism. Normal levels of glycolipids were found in the spleen and liver, which suggest that in Gaucher's disease the abnormal cells make their appearance before the storage of glycolipids takes place. For purposes of classification, this case should be considered as an example of the chronic form of Gaucher's disease in a very young child, in whom thrombocytopenia (usually a late hematological manifestation) appeared within a few days after birth.

Strongyloidiasis. P. Huchton and R. Horn. J. Pediat. 55:602-608 (Nov.) 1959 [St. Louis].

Sixteen patients with strongyloidiasis have been observed at the Vanderbilt University Hospital, Nashville, Tenn., since 1938; 7 were adults and 9 were children, between the ages of 16 months and 8 years. The most constant laboratory finding in this series was eosinophilia, present in 13 patients. Anemia was detected in 11 patients; leukocytosis, in 10; occult melena, in 5; and hypoproteinemia, in 5. The most frequent clinical signs and symptoms were diarrhea, vomiting, and weight loss which were present in 9 patients. Weakness was observed in 8 patients; abdominal pain, in 7; and anorexia, fever, or a semistuporous state, in 5. Edema, melena, urticaria, cough, and dyspnea also appeared in several patients. Constipation, nausea, indigestion, malaise, and headache were less frequent symptoms. The initial clinical impression given by these patients was parasitic infection in 5, nephrotic syndrome in 3, and malnutrition in 4. Acrodynia, celiac syndrome, multivitamin deficiency, pneumonia, and penicillin reaction were listed one time each in a differential diagnosis. In 15 patients the larval forms were found in stool specimens. In the 16th the diagnosis was made at autopsy. Eleven patients were treated with methylrosaniline chloride (gentian violet) only; 3 received diethylcarbamazine citrate (Hetrazan); and 1 received dithiazinine iodide (Delvex); one patient received no treatment. One patient was cured; another was presumed to be cured; 2 were known to be still infected at the time of follow-up; and 4 were presumed to be still infected. Five patients could not be contacted; and 3 children, between the ages of 16 months and 3½ years, died.

The main finding at autopsy in the children who died was infection with Strongyloides stercoralis in the intestinal tract; pulmonary hemorrhage was observed in all 3 children, and duodenal and jejunal ulcers were found in 2. The authors call attention to the potential seriousness of this disease and to its pathogenesis. Prophylaxis of strongyloidiasis is based on the proper disposal of feces, wearing of shoes, and avoidance of contact with soil known to be contaminated. The therapeutic problem has not yet been solved. The newest and most promising anthelmintic is dithiazinine, which must be administered orally since it is damaging to the renal tubules if given parenterally.

Epidemiologic, Clinical, and Laboratory Features of an Epidemic of Type 9 ECHO Virus Meningitis. P. Solomon, L. Weinstein, Ten-Wen Chang and others. J. Pediat. 55:609-619 (Nov.) 1959 [St. Louis].

A group of 64 patients (56 children and 8 adults) was studied at the New England Medical Center during an outbreak of aseptic meningitis, with a significant incidence of skin eruption, which occurred in the Boston area in the summer of 1958. Forty-five patients were males, and 19 females, which confirms the predominance of the disease among males. The great majority of the patients in this series were under 10 years of age, with the highest incidence in the 7-to-8-year age group. The onset of signs and symptoms dated from 3 weeks to less than one day prior to admission to hospital. In 11 patients there was a biphasic course, with the initial illness lasting for a few days, followed by an asymptomatic period, and then by recurrence of the symptoms. The maximal rectal temperature recorded varied between 99.8 and 105.6 F (37.5 and 41 C). Only one patient was afebrile during the entire duration of the disease. All the patients who were able to report on their symptoms complained of headache. Nausea or vomiting or both occurred in 46 (80%) of the 56 patients under 20 years of age, and in 3 of the 8 adults; abdominal pain was present in the children only. Skin eruption was noted in 18 patients (28%), of whom only 1 was over 10 years. Symptoms of respiratory infection were not prominent. Cough, coryza, and sore throat were present, respectively, in 16, 7, and 9% of the patients, with only one adult complaining of coryza. Nuchal rigidity was present in only 11% of the patients. Four patients had manifestations of more extensive involvement of the central nervous system; one had hallucinations, 2 were "talking nonsense," and one (1-year-old) had a generalized seizure with a sudden rise in temperature. The last 3 patients had proved infection due to enteric cytopathogenic human orphan (ECHO) virus, type 9.

Stools and spinal fluid were obtained from the patients soon after their hospitalization. Prepared stool suspensions and spinal fluids were stored at —20 C until inoculation into tissue culture. Acute and convalescent serums were collected at an interval of at least one week. Primary cell cultures of human amnion and Rhesus monkey kidney were used for isolation and identification of the virus, but only the latter was used for the neutralization tests. Titration of the neutralizing antibodies in the serum was also carried out in monkey kidney tissue culture. ECHO virus, type 9, was proved to be the etiological agent in 45 (70%) of the patients studied, by isolation of the virus from the spinal fluid or by demonstration of a fourfold increase in the neutralizing antibody titer or by both. In 5 other patients (8%) ECHO virus was considered the causative agent, despite failure to isolate it from the spinal fluid and despite the absence of a significant rise in antibody. ECHO virus, type 9, was not implicated in only 2 instances in which complete investigation was possible. In 14 patients (22%) no etiological agent could be demonstrated; in 12 of these it had not been possible to obtain adequate material for virologic or serologic studies. This fact, plus the inability to demonstrate other viral agents, and the marked similarity between the clinical pictures observed in this series and those found in previous outbreaks justify the conclusion that the etiological agent in the great majority, if not all, of the 64 patients studied was ECHO virus, type 9.

Congenital Neurocutaneous Syndromes of Childhood: III. Sturge-Weber Disease. D. H. C. Chao. J. Pediat. 55:635-649 (Nov.) 1959 [St. Louis].

Nine patients with nevoid amentia (Sturge-Weber disease) were observed at the Blue Bird Circle children's clinic of the Methodist Hospital in Houston, Texas. Their ages, when first seen, ranged from 7 months to 7 years; the age at onset of the symptoms varied from 2 to 7 months, with the exception of one child in whom the onset occurred at 3 years. The basic angiomatous malformation of Sturge-Weber disease was observed in all 9 patients. All of them presented facial nevus. Neurological findings were hemiparesis in 6 children, atrophy in 5, and increased knee jerk in 1. There was left-sided ocular involvement in all the patients with the exception of one who was born with bilateral buphthalmos. This patient, a 7-year-old boy, received a diagnosis of atypical Sturge-Weber disease because of 3 features in his clinical picture: 1. The distribution of the facial nevus did not follow that of the sensory branches of the trigeminal nerve. 2. The angiomatous malformation was an arteriovenous angioma. 3. Extensive cutaneous lesions, repeated episodes of gastrointestinal hemorrhage, and the fact that the father had telangiectatic lesions suggested that the vascular anomaly might be widespread. The author considers this clinical picture as representing a "variant" of Sturge-Weber disease, and points out the possibility of a transitional hybrid form between the Sturge-Weber and the Osler disease. This child was also the only one in the series to be free from seizures.

Of the 7 children who were of school age when this study was made, only 2 were attending regular classes (including the patient with atypical Sturge-Weber disease). One, who had an IQ of 60-70, was attending a special class; the others were mentally incapable of school work. Three of them were unaware of their surroundings, 2 never developed speech, and 1 could say only one word. Two patients underwent a brain operation, by hemispherectomy in one and by block resection of cerebral lesion in the other. In both patients the seizures disappeared. Two of the 4 patients with glaucoma were operated on for relief from the intramuscular tension. One patient responded well to Diamox therapy, which in this instance served both as an anticonvulsant and as an antiglaucomatous agent. It is the author's opinion that early surgical extirpation of unilateral lesions may prevent functional deterioration as well as bring symptomatic relief from seizures.

Anabolic, Liver-Protective and Antianemic Action of a Combined Treatment with Liver Extract and High Doses of Vitamin B_{12} in Pediatrics. L. Francalancia and R. Cremoncini. Minerva pediat. 11: 944-954 (Sept. 22) 1959 (In Italian) [Turin, Italy].

A treatment with liver extract, combined with high doses of vitamin B_{12}, was given to 6 groups of children with various conditions; the combined dose consisted of 4 units of liver extract and of 0.5 mg. of vitamin B_{12}. The duration of the treatment ranged from 5 to 30 days, and the drugs were administered intramuscularly twice a day, once a day, or every other day. Gain in body weight and marked increase in both hemoglobin and globulin levels, accompanied by improved vitality, appetite, and euphoria, were the results of the treatment in 10 infants, aged between 3 and 11 months, with hypochromic anemia. The treatment resulted in gain in body weight, increase of serum hemoglobin level and of red blood cells, normalization of the Katz formula and of total proteinemia value, disappearance of asthenia and anorexia, as well as regained color of the skin and of visible mucosae in 15 children, aged from 2 to 9 years, who were convalescing from parotitis, measles, smallpox, scarlet fever, paratyphoid, or infectious mononucleosis. The treatment removed acetone-like breath, ketonuria, and vomiting in 8 children, aged from 3 to 6 years. It brought about normalization of hepatic function and improvement in the general state in 4 children, aged between 5 and 7 years, who were convalescing from a severe form of infectious hepatitis. Normalization of the hepatic function and of protein and lipoprotein values, demonstrated by electrophoresis, was obtained in 5 children with tuberculosis. Regained body weight, appetite, and vitality, with improvement in red blood cell count and in hemoglobin and globulin levels, resulted in 7 children with trophic failure. The combined therapy with liver extract and vitamin B_{12} thus produced an efficacious synergic action in these patients.

UROLOGY

Vesico-Ureteral Reflux in Children: Diagnosis and Management. V. A. Politano. J. South Carolina M. A. 55:417-421 (Nov.) 1959 [Florence].

A critical review of the literature indicates that roughly 10 to 12% of children presenting urologic complaints will demonstrate vesicoureteral reflux. Every child with repeated urinary tract infections, residual urine, unexplained fevers, vague abdominal complaints, or flank pain should be studied by cystography. This valuable diagnostic procedure should not be eliminated when intravenous pyelograms have been reported as normal. This condition, if allowed to go untreated, will eventually lead to total renal destruction, either from progressively increasing back pressure or from repeated infections. Neurogenic disorders should be corrected with appropriate drug therapy or surgical modification of the neurological deficit when possible. Residual urine secondary to vesical neck obstruction must be eliminated by catheter drainage, multiple voidings, urethral dilatations, or transurethral or open resection of the vesical neck or other obstructing lesion. Every conservative effort to eliminate reflux should be attempted first. If these measures fail, reimplantation of the ureters by a submucosal tunnel is necessary. The author reports the history of 3 children, aged 4, 6, and 12 years, in whom vesicoureteral reflux was successfully corrected by the creation of a submucosal tunnel.

Results of Treatment of Carcinoma of the Prostate with Diethylstilbestrol Diphosphate (Honvan). H. G. Kletschke. Ztschr. Urol. 52:615-622 (Oct.) 1959 (In German) [Leipzig, Germany].

The author reports on 106 men with carcinoma of the prostate, who were treated with diethylstilbestrol diphosphate (Honvan) in the urologic department of a Berlin hospital between 1953 and 1957. This method of treatment was indicated by metastases in 68 patients, increased serum acid or alkali phosphatase level in 49, renal congestion due to walling in of the ureteral ostiums by the carcinoma in 8, age of less than 60 years in 12, and resistance to estrogen therapy in 38. The patients were given intravenous injections of 2 ampuls (500 mg.) of the drug daily, followed by oral maintenance therapy in 15 patients. Follow-up examinations in the course of 5 years have shown that treatment with diethylstilbestrol is superior to that with estrogens. In 28 (73.8%) of the 38 patients with resistance to estrogen therapy, a favorable response to diethylstilbestrol was revealed by restoration of the acid and alkali phosphatase level to normal in 6, reduced acid and alkali phosphatase level in 4, improved general condition (increase in body weight) in 10, disappearance of pain in 1, and reduced size of the prostate in 7. Microscopic examination of prostatic tissue was performed in 5 patients before and after treatment with diethylstilbestrol alone, and revealed a favorable effect of the drug on the carcinoma tissue. Regression of bone metastases did not occur, but a definite reduction in the size of the soft tissue metastases was observed.

In 10 patients (9.4%) treatment had to be discontinued because of intolerance (continued nausea). Gynecomastia was observed in only 10 patients (9.4%). Fourteen patients (36.8%) died, and in 4 of these administration of diethylstilbestrol had been discontinued because of intolerance. Diethylstilbestrol is a highly effective drug in carcinoma of the prostate. Although a cure of the carcinoma is not possible, the inhibition of growth of the tumor is greater than that obtained with female sex hormone therapy.

Experiences with Diethylstilbestrol Diphosphate (Honvan) Therapy for Cancer of the Prostate. H. Warlitz. Ztschr. Urol. 52:622-629 (Oct.) 1959 (In German) [Leipzig, Germany].

The author reports on 70 men, of the average age of 77 years, with carcinoma of the prostate who were treated with diethylstilbestrol diphosphate (Honvan) in the city hospital of Neumünster/Holstein, Germany, between 1952 and 1959. The following treatment schedule proved satisfactory. An initial course of 8,500 mg. of diethylstilbestrol was given by the intravenous route, with 500 mg. daily for 10 days and 250 mg. daily for an additional 14 days. When local and general findings, roentgenologic examination, and determination of phosphatase values did not show significant improvement, a second course of 8,500 mg. of the drug was given by the intravenous route. It was possible to increase the daily dose to 1,000 or 1,500 mg., provided that the drug was administered in isotonic sodium chloride solution by intravenous drip. After that, maintenance treatment was practiced with oral administration of 1 to 6 tablets of diethylstilbestrol daily.

The results obtained with this schedule justify the statement that diethylstilbestrol diphosphate is a drug which makes properly directed cytostatic treatment possible. Provided that treatment is instituted early, it is possible for the condition of the patients to be maintained in a state in which they are able to work and are free of complaints. Of the 10 patients in whom treatment was instituted in 1952, one is still living. A 5-year cure was obtained in 5 additional patients in whom treatment was started in 1953-1954. Patients with extensive metastases became free of complaints after a short duration of therapy and were able to work. Several of these patients have been treated successfully for more than 2 or 3 years. Although complete disappearance of bone metastases was not observed, sclerosing phenomena in the area of the bone metastases, associated with corresponding changes in the serum alkali phosphatase level, were observed, which may be interpreted as onset of healing. Complete regression of lung metastasis in the course of therapy was observed in one patient. Maximum daily doses of 1,500 mg. were well tolerated, when administered in isotonic sodium chloride solution by intravenous drip.

Therapy must be continued indefinitely, with 1 or 2 tablets given orally daily to patients without metastases, and with 2 tablets given 3 times daily to patients with metastases. Depending on the results of control examinations and determinations of phosphatase values, the maintenance dose must be determined individually. It should be emphasized that normal phosphatase values—even in patients who do not have any complaints—can be deceptive. In 20 to 25% of the patients with metastasizing carcinoma of the prostate, the phosphatase values were normal. Roentgenologic examinations at certain intervals are, therefore, indispensable during ambulatory after-treatment. The cause of the unreliable results of the phosphatase test has not been elucidated. One might have to deal with completely immature carcinomas which have lost their capability of phosphatase formation.

Acid Phosphatasemia in Apparently Healthy Subjects and in Patients with Prostatic Adenoma and Cancer. O. N. H. Ramos. Rev. clín. españ. 74:164-171 (Aug. 15) 1959 (In Spanish) [Madrid].

Determination of serum phosphatase activity was performed on 90 men, 25 of whom were apparently healthy; 15 patients had prostatic carcinoma, and 50 had prostatic adenoma. In the patients with prostatic adenoma, the serum phosphatase was determined before and immediately after the operation and on the 10th day of the postoperative period. In those with carcinoma, only one determination was made, because they were being treated with estrogens. All tests were performed on fasting patients. The values of serum phosphatase activity in the 25 healthy subjects varied between 0.02 and 0.30 Bodansky units, which is considered normal. The preoperative values were within normal limits in the 50 patients with prostatic adenoma; these values increased in the immediate postoperative period, falling again to normal limits 10 days after the operation. The range of phosphatase levels went from 0.35 to 10 Bodansky units in 13 of the patients with prostatic carcinoma, and was normal in the remaining 2. This increased activity was in direct proportion to the advancement of the neoplastic process. The presence of acid hyperphosphatasemia in carcinoma of the prostate is explained by the increased cellular karyokinesis, especially in patients with osseous metatases. This determination of a semiologic element in cancer of the prostate permits the establishment of a certain diagnosis of the disease.

THERAPEUTICS

Antibiotic Combinations: A Study of the Combined Activity of Streptomycin and Chloramphenicol. N. A. Hinton and J. H. Orr. Canad. M. A. J. 81:819-827 (Nov. 15) 1959 [Toronto].

The authors report a case of gastroenteritis with septicemia due to a strain of Escherichia coli (serogroup 026) in an infant. Disk sensitivity tests revealed the pathogenic organism to be sensitive to streptomycin and to chloramphenicol, but resistant to all other commonly available agents. Streptomycin was first given to the patient, and considerable improvement was noted over the next 24 hours, although he remained very ill. Tube dilution sensitivity tests were carried out, and the combined activity of streptomycin and chloramphenicol was determined by mixing equal volumes of them at a concentration of 16 times the minimal inhibitory concentration of each and comparing the minimal inhibitory concentration of the drugs alone with the concentration of each in the first inhibitory mixture according to Welch's technique. No interaction was noted between the components tested. Chloramphenicol was then administered in order to decrease the risk of the emergence of a streptomycin-resistant mutant, and this step was associated with rapid deterioration in the clinical condition of the patient, who died 36 hours after the institution of chloramphenicol therapy. Extensive laboratory studies then were carried out on the effect of streptomycin and chloramphenicol on this strain of Esch. coli in an attempt to correlate the results with this instance of probable antagonism.

A wide variety of effects were obtained when streptomycin and chloramphenicol were allowed to act simultaneously on this strain of Esch. coli. The particular effect observed at any one time was profoundly influenced by the nature of the medium, the relative and absolute concentrations of the agents, and the time of observation. Two predominant effects were observed. Combinations at bacteriostatic concentrations were associated with indifference, whereas combinations of chloramphenicol with bactericidal concentrations of streptomycin showed distinct antagonism. The interpretation of these findings, in terms of the treatment of disease in man, is a hazardous undertaking. However, it would seem not unreasonable to hold that, with streptomycin and chloramphenicol or with a similar pair of drugs which gave the same interaction in vitro, if the infection being treated was one in which a bactericidal effect was essential, one might expect to observe evidence of antagonism when the 2 therapeutic agents were used together. In the case of Esch. coli septicemia reported, the bactericidal action of streptomycin may have been essential to survival, and the addition of the interfering agent was largely responsible for the fatal result. A great many infections, however, will respond satisfactorily to treatment with essentially bacteriostatic agents, and in these infections the antagonistic action of chloramphenicol would probably not be observed. Experimental infections were produced in mice with Esch. coli and a Salmonella species, and the effects of combinations of chloramphenicol and streptomycin on these infections were tested. In these animal experiments both indifference and antagonism were shown.

Special Indications and Risks of Cortisone Treatment in Patients with Carcinoma of the Breast. W. Schermuly. Strahlentherapie 110:393-400 (no. 3) 1959 (In German) [Munich, Germany].

In recent years cortisone and its derivatives have been added to the list of hormone preparations recommended for the treatment of patients with carcinoma of the breast. Besides the possibility of permanent therapy with high doses of 50 to 100 mg. of prednisolone or 100 to 200 mg. of hydrocortisone daily for patients whose tumors do not depend on the production of estrogens, or in whom the effect of procedures aimed at the suppression of estrogens, such as castration or androgen therapy, has been exhausted, cortisone and its derivatives, given in small doses of 10 to 20 mg. daily, may play an important part in the management of some emergencies occurring in the course of metastasizing carcinoma of the breast. These emergencies include damage to the bone marrow, cerebral metastases with neurological and psychiatric symptoms, insufficiency of the adrenal cortex, and hypercalcemia.

The author reports on 2 women, aged 56 and 50 years, respectively, with carcinoma of the breast, who were treated with cortisone and prednisolone at the polyclinic of the University in Marburg on the Lahn. In the first of these 2 patients, the characteristic metabolic changes of osteomalacia, namely, hypocalcemia, hyperphosphatemia, hyperphosphatasemia, and low excretion of calcium in the urine, were elicited by the treatment with 10 mg. of prednisolone per day for more than 4 months, combined with a diet poor in calcium. Severe pain in the left femur suggested a pathological fracture of the femur. Healing of the osteomalacic zone of alteration in the bone, with satisfactory loading capacity, resulted from vitamin D therapy and addition of milk to the diet. Before the institution of this therapy the phenosulfonphthalein (phenol red) test revealed a reduced excretion of the dye (22% instead of 40%). Albumin opalescence to clouding was observed in the urine, and also some leukocytes and erythrocytes. Later one macroscopic hematuria occurred, and still later there was discharge of urinary calculi, which was associated with mild pain. The prednisolone therapy mitigated an infection of the urinary passages, but discontinuation of this therapy caused exacerbation of this infection, and the impaired kidney proved very sensitive to the vitamin D therapy. Long duration of hypercalcuria and formation of urinary stones are predisposing factors. In the second patient who had bone metastases, prednisolone therapy with daily doses of 5 mg. of the drug, combined with a low-calcium diet, elicited within 3 weeks hypocalcemia and an excessive increase in alkali phosphatase level, with a typical slow drop to the initial value within 10 weeks.

In addition to the well-known hazards of treatment with cortisone and its derivatives, hypocalcemia and osteomalacia may occur even in patients who are receiving small doses of these drugs, if sufficient amounts of calcium are not administered. Cortisone and its derivatives diminish the absorption of calcium from the intestinal tract and the uptake of calcium phosphate by the bones. Since much calcium is lost by extensive bone metastasis, hypocalcemia and osteomalacia may occur suddenly. There is also the increased possibility of infection of the urinary tract during cortisone therapy.

PATHOLOGY

Effects of High Protein Intakes on Cholesterolemia and Atherogenesis in Growing and Mature Chickens Fed High-Fat, High-Cholesterol Diets. R. Pick, J. Stamler and L. N. Katz. Circulation Res. 7:866-869 (Nov.) 1959 [New York].

The authors report the results of 4 series of experiments carried out on 210 chickens. The first 3 series were performed on growing birds during weeks of age from 12 to 18, 9 to 14, and 13 to 18 respectively. In these experiments all birds were given a mash containing 1% cholesterol and 5 to 10% fat. The experimental birds were given 34 to 50% supplements of protein (soy bean protein, casein, fish protein, liver protein, or egg albumen) added to the mashes. The contrastest birds consumed mash containing 15 to 20% protein. In the 4th series, mature birds were studied when 21 to 30 weeks of age. The birds were divided into 6 groups, all of which consumed mash containing 1% cholesterol and 5% cottonseed oil. In 3 groups (one of roosters, one of intact hens, and one of oviduct-ligated hens), 54% sucrose was added to the mash, reducing protein content to only 8%. In the other 3 groups (one of roosters, one of intact hens, and one of oviduct-ligated hens), the diet contained 20% protein. The results showed that high-protein intake suppresses hypercholesteremia and atherogenesis in young cockerels o[illegible] holesterol, high-fat diets. This happens with supplementation by any nutritionally good protein and is manifest irrespective of source of cholesterol and type of fat. In mature roosters or hens—as in young growing cockerels—low-protein intake intensifies, and adequate protein intake suppresses, hypercholesteremia and atherosclerosis occurring with high-cholesterol, high-fat diets. However, inhibition of coronary atherogenesis induced in hens by endogenous estrogen secretion continues to supervene, despite low-protein intake. Oviduct ligation prevented intensification of hypercholesteremia and atherosclerosis with low-protein intake.

Tumor Cells in the Blood. I. Salgado, J. F. Hopkirk, R. C. Long and others. Canad. M. A. J. 81:619-622 (Oct. 15) 1959 [Toronto].

The blood obtained from 100 patients was studied for circulating tumor cells at the Royal Victoria Hospital and McGill University, Montreal, during 1958 and 1959. Seventy of the patients had various types of cancer, and 30 had noncancerous disease and were used as controls. No abnormal cells were found in these latter 30 patients. Blood was collected from the vein draining the tumor site in 10 patients with cancer, and tumor cells were found in the blood of 4. Blood was drawn from the antecubital vein in 60 patients with cancer, and tumor cells were found in the blood in 57% of the patients. Thirty-two of the patients in whom blood was drawn from the antecubital vein had carcinoma of the breast, and tumor cells were found in the peripheral blood in 53% of the patients. When the cases of carcinoma of the breast were subdivided, certain differences appeared. Tumor cells were found in the peripheral blood in 63% of the 24 patients with carcinoma of the breast in whom blood was drawn within 9 days after radical mastectomy and who were found to have metastases in the axillary lymph nodes, and in 33% of the 15 patients in whom blood was drawn within 9 days after radical mastectomy and in whom the axillary nodes were not involved. Tumor cells, however, were found in only 25% of the 8 patients with carcinoma of the breast with widespread metastases. No tumor cells were found in the peripheral blood obtained before mastectomy in 5 patients with carcinoma of the breast, but were found in the blood drawn 2 hours after mastectomy in 3 of these patients.

The authors emphasize that great caution should be excercised in applying these findings. The presence of tumor cells in the blood does not necessarily mean that metastases will develop in the patient. Only by following up for many years large series of patients in whom blood has been tested for tumor cells can a satisfactory conclusion be reached as to the prognostic significance of tumor cells in the blood.

BOOK REVIEWS

The Care of Minor Hand Injuries. By Adrian E. Flatt, M.A., M.D., F.R.C.S., Assistant Professor of Orthopedic Surgery, State University of Iowa, Iowa City. With foreword by Carroll B. Larson, M.D. Cloth. $9.50. Pp. 266, with 109 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3; Henry Kimpton, 134 Great Portland St., London, W. 1, England, 1959.

There has been a need for a book on injuries of the hand which can be treated properly without admitting the patient to the hospital. Most of the operations described here can be performed safely under local anesthesia. Since the difference between minor and major injuries is artificial, this book has a wider application than the title would imply. The first section outlines the general principles of care, and the second deals with the treatment of specific injuries. The concise text is complemented by photographs of wounds before, during, and after treatment. Details of many operations are clarified by line drawings. A well-selected list of references is included at the end of the book.

Most of the principles and techniques presented can be applied equally well to more severe injuries of the hand. The four chapters on general principles should be read before proceeding to the description of specific injuries. The latter material is arranged conveniently for quick reference. One safe and practical method of handling each problem is described. There are chapters on injuries from mechanical forces and on burns and hand infections. Some injuries and infections included in the text cannot be managed without general anesthesia, and the author clearly indicates those situations. This book can be recommended highly for interns and residents assigned to an emergency surgical service. It should be an invaluable aid to general physicians and industrial surgeons who meet these emergencies daily.

Sexual Impotence in the Male. By Leonard Paul Wershub, M.D., F.A.C.S., F.I.C.S., Associate Professor of Urology, New York Medical College, New York City. With foreword by Ralph E. Snyder, M.D., President and Dean, New York Medical College. Cloth. $5.75. Pp. 126, with 6 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1959.

The author emphasizes the need for appreciation of the problem of sexual impotence in the male by general practitioners, urologists, internists, and others. The causes are ably classified as organic, quasiorganic, and functional (psychic). The author gives a fine summary of the various organic causes, together with corrective measures when indicated. Quasiorganic causes include postprostatic and other surgery of the urinary tract. Post-traumatic impotence is discussed. The author states that in 90% of all cases sexual impotence is functional but that referral to a psychiatrist is unnecessary except for patients with major psychoses. This book is an excellent guide for any physician who encounters patients with sexual impotence.

The Artificial Feeding of Normal Infants. By William Emdin, M.D., D.P.H., Ph.D. Cloth. 16 shillings. Pp. 113. Howard B. Timmins (Pty.) Ltd., 109 Long St., P. O. Box 94, Cape Town, South Africa, n. d.

The first part of this small volume deals briefly with the theoretical composition of artificial milk mixtures. The second part discusses the practical aspects of artificial feeding (calculation of the formula, choice of milk, and feeding schedules through the first year). The third and final section contains chapters on food additives other than milk, including the necessary vitamins, and concludes with specimen diets through the second year. This manual should be a helpful guide for the artificial feeding of normal infants anywhere.

Hypnosis and Related States: Psychoanalytic Studies in Regression. By Merton M. Gill, M.D., and Margaret Brenman, Ph.D., Cloth. $7.50. Pp. 405. International Universities Press, Inc., 227 W. 13th St., New York 11, 1959.

Memory and Hypnotic Age Regression: Developmental Aspects of Cognitive Function Explored Through Hypnosis. By Robert Reiff, Ph.D., Chief Psychologist, Jewish Board of Guardians, New York, and Martin Scheerer, Ph.D., Professor of Psychology, University of Kansas, Lawrence. Cloth. $5. Pp. 253 International Universities Press, Inc., 227 W. 13th St., New York 11, 1959.

These two books have in common the publisher, time of issuance, general subject matter, and special emphasis on hypnotic regression. For this reason they will be reviewed in relation to each other. The statements on their cover jackets are in marked contrast. The second book is described simply and modestly as a carefully made scientific, theoretical, and experimental study based on certain procedures and yielding results of value in developing further research. Such a description should constitute an invitation to read and learn.

The statements describing the first book are of another character. The tripartition of the title into "Hypnosis," "Related States," and "Psychoanayltical Studies in Regression," with the third part as a subtitle, causes doubt as to the major content of the book, in view of the inherent difficulties of coordinating such divergent topics. One must consult the book itself to discover the actual emphasis of meaning in the title. The front inside flap offers a description of the book's content as the psychoanalytical "interpretation of data gained in an extensive research project on hypnosis. They [the authors] re-examine their basic frame of reference, clarify some of its assumptions" and thus "make a genuine contribution not only to the understanding of the variety of hypnotic phenomena but also to the nature of regression." No clarifying statement is suggested as to how all this is done. There is the added statement, "The breadth and scope of this book are evident from the areas which are extensively covered." There follows a 20-item listing. Some of the items are fugues and multiple personalities and hypnosis; brain washing and hypnosis; Balinese trance states and hypnosis; structure of the ego and its subsystems; and five metapsychological points of view in psychoanalysis. Since all this is to be covered in 374 pages, the description tends to imply superficiality and inadequacy.

"Memory and Hypnotic Age Regression," an investigative study of memory by means of hypnotic regression, is written so that it is interesting, stimulating, and informative to the psychologically trained and to the lay reader. The survey of literature is pertinent and comprehensive, and divergent views are carefully appraised and objectively presented. The first three chapters discuss lucidly (1) static and dynamic conceptions of memory, together with environmental and experiential significances, (2) forms and kinds of memory and reconstruction and developmental considerations, and (3) hypnotic age regression in relation to hypermnesia, regressive phenomena, validity of manifestations, and cognitive functioning. Each of these chapters is explanatory and definitive. They clarify the nature of the total study, the available background of scientific studies, and the various divergent conceptual understandings. Of particular interest is the scientific consideration given to psychoanalytical concepts and formulations, something greatly needed and in marked contrast to the adulatory, dogmatic presentation of similar material in the other book.

The fourth chapter is a systematic evaluation, in terms of the possibilities indicated by the past experimental work of others and the thoughts of the authors, of the problems of method, technique, and validity of procedure in presenting tasks, inducing trances, and selecting subjects. The next chapter adequately states the method of investigation in relation to hypotheses, general procedure, and the rationale for the experimental treatment of data. The sixth and seventh chapters present the experiments on emotional and cognitive functioning by a series of ingenious and revealing tests, the experiments on contextual recall by questionnaires, and an appraisal of the validity of experimental findings, including recall of forgotten skills. The results in both types of experimental investigation clearly indicate hypnotic regression to be a valid phenomenon of significant value in the study of memory.

Chapter 8, Methodological Considerations, discusses these experiments in both retrospect and prospect, emphasizing the often overlooked importance of how experimental results are obtained rather than simply their failure or success. The last chapter discusses theoretical considerations in terms of past efforts to theorize and the opportunities offered by the experimental findings reported for new theoretical and experimental approaches to memory and related problems of neurophysiology. The bibliography is well selected and representative, and the book is indexed.

"Hypnosis and Related States" is a disappointing book. It is neither a study of hypnosis, nor a study of related states, nor a psychoanalytic study of regression. It is simply a laborious effort to translate into psychoanalytical terms and theories, by means of simple dogmatic assertions, the authors' various random observations on hypnosis. For example, on page xxiii of the introduction, the following statement appears.

> Our definition of hypnosis is an attempt to integrate the ego-psychological concepts just outlined with the usual view of hypnosis as transference. *The hypnotic state is an induced psychological regression, issuing, in the setting of a particular regressed relationship between two people, in a relatively stable state which includes a subsystem of the ego with various degrees of control of the ego apparatuses.* Obviously this definition is a highly condensed statement, each part of which requires considerable elaboration, a task we undertake in Chapter 5, devoted to the metapsychological theory of hypnosis.

Their own observations of hypnosis, they state, were made incidentally, for the most part, during the long-time therapy of psychiatric patients, on some of whom hypnosis was either attempted or briefly used as an adjuvant therapy. No body of either experimental or observational data is presented. The bibliography, extensively quoted throughout the book, is primarily psychoanalytical in character. The literature on hypnosis, particularly of the last 10 years, has been largely neglected. Examination of the excellent index discloses that posthypnotic suggestion, a major hypnotic phenomenon, is mentioned twice and discussed once in a brief paragraph on page 104. Ego apparatuses, an undefined speculative psychoanalytical concept, receives mention more than 40 times and many paragraphs of discussion.

The Hypnoanalysis of an Anxiety Hysteria. By Fredericka F. Freytag, M.D. Foreword by Milton H. Erickson, M.D. Cloth. $6.50. Pp. 413. Julian Press, Inc., 80 E. 11th St., New York 3, 1959.

During the last 100 years there have been periodic increases in interest in the subject of hypnosis. As a result of the present wave of interest, which began after World War II, numerous articles and books have been published. These publications range from excellent scientific discussions to the Bridey Murphy type of popularization. The present volume is an attempt to record what is called the hypnoanalysis of a single patient. Such reporting s always beset with difficulties, as this volume demonstrates. The technique used seems to be for he most part the induction of a trance state in which the patient believes that he is living in the past. The psychotherapeutic aspects which are osensibly based on psychodynamic principles are questionable. Parts of the book read like a movie cript. The psychotherapy seems to consist of a eries of lectures on psychoanalytic psychology presented to the patient by the therapist. Though he patient is a physician, it is difficult to visualize he value of the various discussions in terms of ego, superego, and other technical phraseology. It hould be noted that Freud, whom the author does not mention, gave up the technique of hypnoanalyis of patients with anxiety hysteria in the 1890's. Of the 22 references, 11 refer to personal communications from one correspondent. Too many books are being written on the subject of hypnosis.

The *Biology of Myelin.* Edited by Saul R. Korey, M.D., Professor of Medicine (Neurology), Albert Einstein College f Medicine, New York. With fifty-one participants. Progress n Neurobiology, volume IV. Series editors: Saul R. Corey, M.D., and John I. Nurnberger, M.D., Chairman and Professor, Department of Psychiatry, Indiana University School of Medicine, Indianapolis. Cloth. $9.50. Pp. 405, with 116 llustrations. Paul B. Hoeber, Inc. (medical book department f Harper & Brothers), 49 E. 33rd St.; New York 16, 1959.

This book comprises 12 papers presented in a ymposium sponsored by the National Institute of Neurological Diseases and Blindness. The authors epresent every field of basic health science as well as related clinical fields. The discussions following he presentations greatly add to the value of the essays. As for all books of this type, a concise review is difficult because the papers are mainly progress reports which the authors do not summarize at the current stage and because there is both dissociation and overlap among them.

For anyone not working primarily in this field t may be a source of amazement that so much can be found in so little. The comparatively inert and uninteresting envelope of the axone has now become a tremendously complex membrane evolving from the plasma membrane of the Schwann cells, or, as Schmitt now proposes, satellite cells. The amellate character of the membrane must exercise great influence on ionic exchange. The nodes of Ranvier are suggested as infoldings of the plasma membranes. Less regular extensions of the membrane into the cytoplasm, often related to accumulations of mitochondria, are also observed. Thus when the essayists speak of the ultrastructure of myelin, it is comparable to the first suggestion of subdividing the atom. Even the single-layered membrane seen in prepared sections for the light microscope is now seen to consist of two layers, each 25 A thick, associated with protein, and separated by a less dense space associated with lipids. Previous polarization and x-ray diffraction studies presaged the suggestion that myelin is a part of the sheath cell and not an axonal secretion. Lamellate organization of protein and lipid occurs also in retinal rods and in chloroplasts.

Nodes of Ranvier are no longer considered as masked naked gaps but are clothed in Schwann cell plasma membranes that condition their vulnerability to ionic influences. The study of mutations has fathered the concept that myelin faults and neurological changes may have genetic origin. When occurring spontaneously in animals, neurological changes are often associated with other abnormalities known or believed to be mutant. Chemical studies of nerve tissue in time relation to myelin formation have been too fragmentary to permit conclusions except that cerebrosides, proteolipids, trypsin-resistant protein, phospholipids, and cholesterol are involved in the process of myelinization. Many study projects are already tied to these observations in relation to age changes in nerve tissue. Wallerian degeneration, axonal regeneration, and experimental encephalitis also received much attention, but definite results reducible to summarization are not yet available.

This is an intensely interesting and valuable series of studies giving promise of specific information in the future. To one who witnessed the skepticism with which early electron microscope studies were received, it is gratifying to see how decisively it has contributed to advances beyond the best that light microscopy could accomplish. The use of illustrations would have been far more helpful to the reader if all types were placed in one numbering system designated by page number instead of the tripartite system used here. Index tables would then be simplified. The growing use of capital letter abbreviations for long complex names, phrases, and technical terms poses a problem for readers not acquainted with the latest, which could be resolved by the inclusion of a glossary briefly explaining each abbreviation.

The Pharmacology and Clinical Usefulness of Carisoprodol. Edited by James G. Miller, M.D., Ph.D., Director, Mental Health Research Institute, University of Michigan, Ann Arbor. Symposium sponsored by Wayne State University College of Medicine and University of Michigan Medical School, Department of Postgraduate Medicine, held in Detroit, Michigan, July 1, 1959. Cloth. Pp. 185, with illustrations. Wayne State University Press, Detroit 2, 1959.

The papers which compose this book deal almost exclusively with reported observations on a new muscle-relaxing, pain-relieving agent called carisoprodol. The pharmacology and clinical studies included cover a wide range of disciplines and observations, including use of the drug in inflammatory and neurological disorders. In general, carisoprodol exhibits some of the properties of its predecessors, mephenesin and meprobamate. The point that the reports are of a preliminary character is emphasized in a summary of the conference that appears with a general index at the end. Some of the papers are followed by references and discussions. These features should increase the value of the book for those who have a particular interest in skeletal muscle relaxants and their use as tranquilizers.

The book achieves its purpose of bringing together, within a single cover, a series of related reports on a new drug. It should be of greatest interest to pharmacological and clinical investigators, chiefly as a pattern for further studies of the subject and related drugs.

Disorders of the Temporomandibular Joint: Diagnosis, Management, Relation to Occlusion of Teeth. By Laszlo Schwartz, D.D.S., Clinical Professor of Dentistry, Columbia University, New York City, and eighteen contributors. Introduction by Charles Ragan, M.D., Professor of Clinical Medicine, Columbia University. Foreword by Harry Sicher, M.D., D.Sc., Professor of Anatomy, Loyola University School of Dentistry, Chicago. Cloth. $15. Pp. 471, with 458 illustrations by Robert J. Demarest. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, England, 1959.

This well-documented book was written to be used as a guide for diagnosing and treating disturbances of the temporomandibular joint and its associated structures. It is divided into 37 chapters and is well illustrated. It should be read by anyone who is attempting to diagnose and treat pains in the area of the face and jaw as well as of the temporomandibular joint. It discusses the occlusion of the teeth, the muscles of mastication and their relationship to the temporomandibular joint, and the differential diagnosis of the various causes of pain in the facial area which might be confused with pain in the joint. It covers the methods of treatment, including occlusal grinding, splints, and physical therapy. The diagnosis and treatment of the various disturbances which contribute to pain in the joint, specific diseases and injuries in the joint, and the complications of treatment are also described. An enormous amount of information is included in this volume. Some of the long accepted facts are questioned, and this long overdue book should stimulate more investigation of the temporomandibular joint area.

Cutaneous Manifestations of the Malignant Lymphomas. By Samuel M. Bluefarb, B.S., M.D., F.A.C.P., Associate Professor of Dermatology, Northwestern University Medical School, Chicago. With introduction by Steven O. Schwartz, M.D. Publication number 330, American Lecture Series, monograph in Bannerstone Division of American Lectures in Dermatology. Edited by Arthur C. Curtis, M.D., Chairman, Department of Dermatology and Syphilology, University of Michigan Medical School, Ann Arbor. Cloth. $15.50. Pp. 534, with 47 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1959.

Although much remains to be learned about malignant lymphomas, most of what is known may be found in this book. It contains information about mycosis fungoides, Hodgkin's disease, and lymphosarcoma. It includes a short discussion of the immunological status of these related conditions. Etiological considerations, clinical features, symptoms, treatment, and other aspects are described methodically and documented with an unusually extensive bibliography. The author's comments and illustrations are to the point. Individual case histories and the myriad of facts make for slow reading, but the data presented is adequate compensation. Though this source book was written primarily for the dermatologist and other investigators, all persons interested in malignant lymphomas should find it full of useful information.

Metabolic Care of the Surgical Patient. By Francis D. Moore, M.D., Moseley Professor of Surgery, Harvard Medical School, Boston. Cloth. $20. Pp. 1011, with 143 illustrations by Mildred Codding, A.B., M.A., Surgical Artist, Department of Surgery, Harvard Medical School. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, England, 1959.

This is a superb new book which covers material not previously available in one volume. It is extremely practical since it discusses problems that are encountered in daily care of the patient, as well as how to search for and combat irregularities. Knowledge in this surgical area has been greatly expanded in the past 15 years. This book, by authorities in the field, is up to date and well organized.

A wide range of subjects, including surgical endocrinology and metabolism, is covered. Important subjects such as normal and abnormal convalescense, hematological findings, fluid and electrolyte management, and repair of tissues and wounds are presented in detail. An outstanding feature is the clear and concise way in which the physiological bases of various conditions are explained. Diseases of the gastrointestinal tract are given special consideration providing ready answers for many problems. The book discusses all processes affecting surgical convalescence, including dehydration, starvation, potassium deficiency, healing, adrenal failure, anemia, and shock. All types of feedings, including tube feedings, are discussed in detail. Case histories are used to illustrate principles of treatment and day-to-day problems. There are sufficient illustrations, charts, and tables to clarify and demonstrate points of interest plus an extensive bibliography at the end of each section. The book is practical and comprehensive and should be of great value to everyone involved in the care of the surgical patient.

QUESTIONS AND ANSWERS

NOCTURNAL ARTHRITIC PAIN

To the Editor:—*I have had rheumatoid arthritis for 28 years and have been taking aspirin in a dosage which is sufficient to alleviate discomfort during the day but does not control the pain during the night. An increase in the dose causes indigestion, and I get no relief from enteric-coated tablets. What medicament should I take?*

M.D., Illinois.

Answer.—There is a recently produced salicylate tablet which is covered with two or three coats of a substance which delays the absorption of the active ingredient of the tablet for several hours. This type of salicylic acid derivative should be tried. Although enteric-coated aspirin may not have been of benefit, the new preparation, which consists of potassium salicylate, 0.30 Gm., ascorbic acid, 0.05 Gm., and potassium para-aminobenzoate 0.3 Gm., made up in tablet form, may be helpful. A small dose of a corticosteroid, such as methylprednisolone, one 2-mg. tablet at 8 or 9 p. m. before retiring, may ease the night pain and stiffness. A suitable sedative, such as pentobarbital, secobarbital sodium, or glutethimide, can be taken as an adjunctive medicament to ease discomfort during the night. Many patients are helped by taking a warm tub bath before retiring.

AIR TRAVEL AND MENSTRUAL IRREGULARITY

To the Editor:—*Has travel by propeller plane or jet aircraft ever been considered a direct etiological factor in menstrual irregularity?*

M.D., Illinois.

Answer.—In over 20 years of association with stewardesses or hostesses on commercial airlines in the United States, I have no evidence that flying in any type of aircraft (propeller, jet propeller, or jet) is an etiological factor in menstrual irregularity. These women are 18 to 30 years old, an age in which a normal amount of menstrual irregularity occurs. If menstrual irregularity occurs at the time they begin work in the airline, we feel that it has no relationship to flying and that it would have occurred had they been working in one of the offices on the ground. During the employee physical examination the degree of dysmenorrhea which a woman may have is ascertained, because she is expected to continue working whether she is menstruating or not to maintain regularly scheduled flights. The Air Transport Association of America has a medical committee which is composed of the medical directors of all the major airlines. This committee has no evidence to date which contradicts this answer to the query.

OPIUM SMOKING

To the Editor:—*A patient with advanced and incurable carcinoma suffers occasional bouts of intense pain. He is unable to retain orally administered narcotics. Hypodermic injections of narcotics for relief from pain are effective but often no person qualified to give these injections is available. Can your consultants suggest whether tinctura opii (USP) is a suitable raw material for opium "smoking"?*

H. H. Neumann, M.D., Elmont, N. Y.

Answer.—No proposal has ever been made in the formulation or application of national or international measures designed to control smoking of opium (or opium preparations suitable for smoking) to permit exceptions because of the alleged medical need for such a use of this substance. Early in the history of our internal revenue laws a prohibitive tax was placed on the manufacture of smoking opium, and our Narcotics Import and Export Act prohibits the possession, receipt, or importation of opium prepared for smoking; it is subject to summary seizure and forfeiture. The laws of the United States, therefore, do not recognize any medical use for smoking opium or opium prepared for smoking.

MIGRAINE HEADACHES

To the Editor:—*Would you have a consultant give an appraisal of desensitization treatment for the prevention of migraine headaches?*

J. B. Eviston, M.D., Huntington, Ind.

Answer.—There is no proof that a patient who has migraine headaches is allergic to histamine, nor has it been established that repeated injections of histamine will desensitize such patients. On the other hand, some physicians have reported fair to good results in patients who have migraine headaches or histaminic cephalalgia. Most allergists believe that the proper therapy for true or typical migraine consists of four steps: (1) discovery of the cause by a carefully taken history, with subsequent elimination of certain foods and deliberate feeding, one at a time, of suspect foods; (2) more or less permanent removal of any foods which seem to cause the migraine; (3) control of any contributory factors, such as emotion (The importance of the emotional factor decreases if the causative food, e. g., milk or pork, is discovered and removed.); and (4) use of ergotamine tartrate for acute attacks. (If the cause is discovered, ergotamine also becomes of secondary importance.)

INFANTS WITH FLATFOOT

To the Editor:—*I would like to know what treatment for flatfoot should be prescribed for a 15-month-old infant who weighs 27 lb. (12.3 kg.), has been walking for three months, and has no leg or hip deformity. Shoes with a medial wedge, worn for three months, have produced little change in the child's condition.*

Thomas C. Stevenson, M.D., Menlo Park, Calif.

Answer.—The prescribed treatment of a medial wedge on the medial border of the sole of the shoe should be continued until the child is 2 to 3 years of age; the wedge should be on the medial side of the heel as well as on the sole of the shoe. The mother should be instructed to manipulate the great toe and forefoot in the varus position daily, and the child should not go barefoot except in the evening when the mother can instruct him to walk on the outer side of each foot, with the feet turned inward. When the patient is 3 years old, some form of lift may be applied inside the shoe for support of the arch to prevent pronation.

IMMUNE MILK FOR ARTHRITIS

To the Editor:—*Please give me an appraisal of immune milk as a remedy for arthritis.*

J. H. Roberts, M.D., Cotati, Calif.

Answer.—Treatment with immune milk for patients with rheumatoid arthritis is based on several unproved hypotheses. It assumes that the disease is caused by deposition of an insoluble antigen in the tissues of the joints. The antigenic substance is assumed to come from streptococcic organisms. The streptococcic antibodies are produced in the cow by injection of a commercial polyvalent vaccine into the teat canal, prior to the cow's coming fresh with milk. When the patient ingests immune milk, it is also assumed that the antibodies are assimilated and when they reach the joints an antibody-antigen complex is formed.

In the instalment of "Primer on the Rheumatic Diseases" appearing in The Journal, Oct. 31, 1959, page 1210, the cause of rheumatoid arthritis is listed as unknown. That hypersensitivity may be a factor is mentioned, but this possibility remains in the realm of research. Treatment by means of streptococcic antibodies is not listed in the section on therapy.

Immune milk is not recommended as a therapeutic agent for the management of patients with rheumatoid arthritis.

FINGERNAIL GRAFTING

To the Editor:—The Journal *(92:1253 [April 13] 1929) contained an article by Sheehan about grafting a thumbnail. A patient has a similar problem that might be cured by this procedure. Could you supply additional information?*

M.D., Florida.

Answer.—I have studied this article several times and believe that the physiological principles it propounds and the treatment based thereon are sound and well carried out. A consultation with a plastic surgeon would be one source of information.

Answer.—I have never attempted to transplant a fingernail and do not know of anyone who has. If the procedure described in the above mentioned article were really successful, there would probably be other reports about it.

TREATMENT OF SPLIT FINGERNAILS

To the Editor:—The Journal, *April 18, 1959, page 1967, contained a question regarding a remedy for split fingernails. A successful method of treatment was published about 25 years ago in a yearbook of surgery. The two sides of the nail were sutured together at the distal end. I am not sure whether the surgeon drilled holes in the nail or simply used a needle to carry the thread through the nail. Additional sutures were placed in the nail as it grew out, and those put in previously remained in that portion of the nail which was subsequently trimmed. The article contained an illustration which showed the presence of at least two, and probably three, successive sutures present at the same time.*

Harry F. Becker, M.D., Los Angeles

Note:—Information on this question was identified in an article by Dr. Wilson A. Swanker entitled, "Reconstructive Surgery of the Injured Nail." The article was prepared by the *American Journal of Surgery* and published by the Yorke Publishing Company, Inc., New York.

PICA

To the Editor:—*A 2-year-old child eats paper—of any and all types. Please comment on the problem of children eating materials such as dirt, crayons, and paper.* *M.D., California.*

Answer.—The patient who eats paper has a disease that might be called papyrophagia; the nomenclature follows the established names, e. g., ingestion of dirt is chthonophagia and that of hair is trichophagy. The child should eliminate the paper with normal intestinal function since there is partial digestion of the cellulose constituents of paper. Depending on the amount of paper and the kind of ink consumed, the printer's ink may be a cause for concern. Ordinary paper without print can cause obstruction of the gastrointestinal tract by bolus formation, which would result in constipation and associated disorders. Eating of unusual materials frequently occurs in mentally retarded children. If the child is educable, all that needs to be done is to provide better supervision of his play and attention to his emotional needs. Since iron deficiency and infestation with intestinal worms can be organic causes for pica in children, a complete physical examination should be made.

BETA HEMOLYTIC STREPTOCOCCI AND PENICILLIN

To the Editor:—*Are there any authenticated instances of beta hemolytic streptococci which are resistant to penicillin?*

Arthur Koffler, M.D., Stamford, Conn.

Answer.—No authentic instances of beta hemolytic streptococci significantly resistant to penicillin appear to have been reported. Routine tests show some variation in the degree of sensitivity of different strains of hemolytic streptococci to penicillin, but this variation is not great enough to suggest significant degree of resistance. There is no reliable evidence of in vivo resistance to penicillin by hemolytic streptococcic infections that are not attributable to factors other than lack of sensitivity of the organism.

SPANKINGS

To the Editor:—*What is the current opinion about the disciplinary effect of spanking a disobedient child?* *M.D., New York.*

Answer.—Wholesome obedience from a child depends primarily on his love and respect for his parents, developed through the parent's devotion, reasonableness, firmness, and consistency. Punishment becomes necessary only when this system temporarily fails. Some parents rear well-behaved, well-adjusted children without administering any physical punishment; others (especially those who themselves were spanked occasionally in their childhood) naturally turn to this method. It is not harmful if the parents are generally fair and affectionate. A few parents use physical punishment excessively, because they are hostile or because they lack basic leadership and control, which is usually due to the fact that their own parents did not provide a good model of child-rearing. In the absence of mutual respect and other positive elements of good discipline, punishment is ineffective and often engenders further antagonism in the child-parent relationship. Spanking becomes clearly undignified and self-defeating when its use is extended to the adolescent.

The physician can be helpful not by arbitrarily approving or disapproving any one form of punishment used by his patients but by clarifying the problem of parent and child. When discipline fails completely, it is usually necessary to seek the aid of a family social agency or child guidance clinic.

INGESTION OF PLASTER OF PARIS

To the Editor:—*What symptoms will follow ingestion of powdered plaster of paris and what treatment can be recommended?*

M.D., New Jersey.

Answer.—The ingestion of plaster of paris (anhydrous calcium sulfate or dihydrate with about 5% of water [0.5 mol]) may result in obstruction of the patient's upper intestinal tract, particularly at the pylorus, because this compound hardens quickly after absorption of moisture. Treatment consists of giving glycerin or gelatin solutions or large volumes of water to delay the setting process; surgical removal of the material may be necessary.

CYANOSIS OF FINGERNAILS

To the Editor:—*What causes cyanosis of the nail beds in an otherwise healthy young woman? She has no cyanosis of lips, ears, or fingers or subjective complaints. There are no objective findings.*

C. J. Kilduff, M.D., Las Vegas, Nev.

Answer.—Cyanosis limited to the nail beds probably rules out systemic disease as a cause for the condition. Absorption of chemicals containing silver or aniline dyes may result in cyanosis of nail beds but will also cause extensive changes in skin color. Additional facts would be necessary for a specific answer to this question. Does cold bring on the cyanosis? Can it be relieved by placing the hands in warm water? Has it been present since birth or childhood? Is the cyanosis present constantly or is it relieved by certain factors? These facts would aid in determining whether localized vasospasm is a factor. Capillary microscopy might determine whether the patient has any congenital capillary or venule anomaly involving the vascular system of the nail beds. Cyanosis will disappear when pressure is applied to the nail with a glass slide; pigment in the nail will not. The patient's occupation may involve exposure to pigments or chemicals which can color the nail.

TREATMENT OF TYPHOID CARRIER

To the Editor:—*A 43-year-old man who had typhoid fever in 1938 moved to California in 1955, where he has had a variety of jobs, only the last of which involved the handling of food. What treatment, medical or other, is most effective in typhoid carriers?*

D. D. Carr, M.D., Las Vegas, Nev.

Answer.—Persons who have had typhoid fever may become temporary carriers up to six months after convalescence, when the condition may clear spontaneously. If the carrier status persists longer than one year, the patient is classified as a chronic carrier; two-thirds to three-fourths of these will continue indefinitely to shed bacilli from an infected focus, usually the gallbladder. They continue to do so, in spite of all other types of therapy, until the gallbladder is surgically removed.

When the nidus of infection is not the gallbladder, it is often in the solitary lymph follicles in the colon or in lesions in the small intestine. The bacillus sometimes persists in patients with nephrolithiasis, and as urinary carriers they are usually refractory to drug therapy.

Typhus Bekämpfung in Südwesten Deutschlands, Arbeiten aus dem Kaiserlichen Gesundheitsampte, vol. 41, Berlin, Julius Springer Verlag, 1912.

SALIVA OF INCREASED VISCOSITY

To the Editor:—*A 48-year-old woman has complained for eight or nine months that her saliva is thicker and more sticky than usual and, at times, has a slightly whitish, discolored appearance. She is healthy and there is no evidence of swelling, infection, or neoplasm in the salivary glands. The results of a basal metabolism test were recorded at —12 to —15. Is this condition serious?*

Walter D. Hankins, M.D., Johnson City, Tenn.

Answer.—This woman has xerostomia, which is the absence or diminution in quantity of salivary secretions, causing a saliva of sticky consistency and difficulty in mastication and swallowing. On examination of the patient, the saliva usually "strings" when touched with a throat stick, and only a small amount of viscid saliva can be expressed from the principal salivary ducts.

Idiopathic xerostomia is a rare condition which is most commonly seen in elderly women. The onset is insidious, progressive, and, once established, permanent and irreversible. Treatment is limited to improvement in oral hygiene, the use of soothing mouthwashes, and improvement of nutritional status.

Acquired xerostomia is usually temporary, except when it occurs after radiation therapy. It may occur in patients improperly treated for dehydration, in patients with severe emotional disturbances, or in patients receiving drugs such as antispasmodics, antihistaminics, and opium derivatives. Treatment is directed primarily at the underlying disease or condition, with augmentation of the fluid intake induced by drinking unsweetened lemonade, chewing gum, or sucking juice from a lemon. Administration of nicotinic acid or pilocarpine hydrochloride may be of benefit.

A basal metabolism rate of —12 to —15 is probably not of any pathological significance in this woman, since she is completely symptomless with regard to her thyroid status.

POLYURETHANE PLASTIC FOAM FOR FRACTURES

To the Editor:—*Are there any drugs that can therapeutically stimulate formation of new bone? If not, is there some way to enhance formation of bone callus at the site of fracture, thus speeding the recovery of a patient?*

M.D., New Mexico.

Answer.—There appears to be no drug that has the specific pharmacological property of stimulating new bone formation.

There are many drugs that can be administered to correct specific causes of delayed healing, such as infection, abnormal calcium metabolism, and abnormal blood clotting mechanisms.

A substance that might be considered as decreasing the patient's period of immobility is polyurethane plastic foam (Ostamer), which is a strong plastic used to bind and stabilize fractures of the long bones of the upper or lower limb. It is used in fractures requiring open reduction and must be forced into the medullary canal in both directions from the site of the fracture to produce and maintain good fixation. The plastic foam supposedly acts as a framework for growth and repair of new bone by which it is replaced.

However, use of this substance seems to offer little in the routine management of fractures and other orthopedic problems that cannot be accomplished equally well by standard methods. Considerable technical problems attend its use; some physicians have reported a high incidence of complications. Consequently, it has been suggested that, until further experience is acquired, it be reserved for trial in carefully selected cases, such as of nonunions that have not healed despite several competent bone grafts, or of pathological fractures caused by metastatic malignant tumors.

Drug Industry Hearings . .
Administration Weighs Medical Plans . .
Keogh Bill Prospects . .

DRUG INDUSTRY SPOKESMAN CITES PROGRESS; SCORES CRITICISM

The president of the Pharmaceutical Manufacturers Association told Congress that the drug industry has served the public interest by driving prices down to the lowest possible level. "Americans would be paying a billion dollars a year more for drugs if the price of medicine in the past few years had gone up only as much as the total cost of living," said PMA President Dr. Austin Smith.

Testifying before the Senate antimonopoly subcommittee headed by Sen. Estes Kefauver (D., Tenn.) as it resumed its hearings on drug prices, Dr. Smith criticized charges leveled against drug companies at subcommittee hearings earlier this year. "There is grave danger," he said, "of misinforming the public when attention is directed toward the single product of a single company . . . without relating these to the many thousands of products produced by the entire industry."

Since 1947, the industry has spent about 1 billion dollars in research alone, Dr. Smith pointed out, adding that the major risks in the field must be met out of profits. In 1958, out of 114,600 substances tested, about 40 became marketable drugs—a failure ratio of 2,865 to one. Also, competition rapidly obsoletes a marketable drug, the witness noted.

Replying to accusations of huge profits, Dr. Smith said that between 1948 and 1958, for example, wages rose 70% and construction costs 64%, while wholesale drug prices went up only 3%.

As for advertising, "Ours are about the only ads in America that tell not merely the good things about our product, but deal exhaustively with the bad ones as well. Toxicity, side-effects—all must be exposed in full detail. Some, of course, are 'reminder ads,' intended to recall to the reader's memory the more extensive clinical findings he has seen earlier.

"But the most important advantage of medical advertising is that it brings new product information to the doctor's attention almost as soon as the new drug has received approval by the Food and Drug Administration. This is not true of scholarly articles which appear in the editorial content of medical journals. The time lag here ranges between six months and a year."

Here are some of Dr. Smith's statements on other important aspects of medical practice and drugs:

Detail Men: Surveys have shown that the detail man is the physician's first and most important source of new product data. The benefits of detailing are not matched by any other medium. In a few minutes the detail man can acquaint the doctor with the capacities and the limitations of a new drug.

Aids to Medical Practice: Educational funds support a large part of most medical society programs through journal advertising and exhibit space. They contribute substantially to the economic existence of most medical journals . . . provide almost all available closed-circuit educational TV for physicians . . . provide medical teaching films, circulation of reprints of medical reports, medical seminars, and finance millions of samples used by doctors to determine their patient's response to a drug before the patient spends money to fill a prescription.

Generic Terms: Under the American system of medical care, the physician alone arrives at the diagnosis and he alone decides precisely what drug is to be prescribed for his patient . . . From the standpoint of the physician and pharmacist, the use of generic equivalents would in no way lessen but might well increase their liability, because it could increase the chances for unfavorable reactions, to the detriment of the patient. . . .

Competition: . . . . I find it paradoxical that on the one hand our industry is charged with being noncompetitive, while at the same time our advertising and promotion—use of time-tested American instruments of competition—are singled out for special criticism.

HIGH-LEVEL STUDY ON FORAND BILL ALTERNATE

There were increasing signs that the administration has decided to push for some type of program in the field of health care for the aged this year.

Of five plans reported to be before the budget bureau and White House for consideration, four involved hiking social security taxes to finance partial medical and hospital care for aged social security beneficiaries. Although this also would be done under the disputed Forand Bill calling for government medicine, the administration plans allegedly would allow the states to administer actual operation of the aged aid programs. Under the Forand measure, of course, the federal government would operate as well as finance the scheme. It is opposed, by the American Medical Association and many other groups, as a first step toward a complete federal medical setup in this country, among other objections.

Another plan receiving top-level administration study, according to reports, would provide a 90-million-dollar program of federal grants to help the states to expand their present public assistance programs for indigent older persons.

BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, New York

Arthur S. Flemming, Secretary of Health, Education, and Welfare, has asserted frequently that he planned to send Congress an aged health bill this session, but at the same time he has reiterated the administration's opposition to the Forand-type approach. Generally speaking, any plan that would use the federal social security mechanism for financing has been regarded as a Forand-type bill, since it involves compulsory social security contributions.

The reports of administration consideration of these plans were neither officially confirmed nor denied by the administration as of this writing, but high sources confirmed them informally.

The alternatives involving the social security program would cost an estimated 400 million to 1 billion dollars a year derived from higher Social Security taxes. The Forand bill to expand the social security program to include partial financing of some health care for aged beneficiaries would cost about 2 billion dollars annually.

What effects submission of any administration program would have on Congress was a matter of conjecture, but some observers said it would probably touch off a full-scale debate on the entire matter of federal intervention in the private practice of medicine. The House Ways and Means Committee was scheduled to consider changes in the social security program at closed-door meetings in late March.

PROSPECTS BRIGHT FOR SELF-EMPLOYED RETIREMENT BILL

The Senate Finance Committee charted a March session on legislation to encourage the self-employed to set aside money for retirement. Lawmakers predicted that a majority of the Senate favors the measure.

There were indications that the bill might be brought up for action in the near future, although exactly what form it would take was uncertain. The House last year overwhelmingly approved the bill sponsored by Rep. Eugene J. Keogh (D., N. Y.) and the late Rep. Richard M. Simpson (R., Pa.). The Senate Finance Committee, led by Sen. Harry F. Byrd (D., Va.), held hearings on it last year but took no action, in part because of administration opposition.

The bill is designed to give self-employed persons like physicians, dentists, lawyers, and farmers tax treatment similar to that now provided salaried persons. Corporation contributions, often 100%, are tax deductible, but there is no tax deduction or deferral for persons who are in business for themselves.

Under the House-passed bill, self-employed persons would be entitled to tax deferrals on up to $2,500 a year or 10% of net income. A maximum of $50,000 could be set aside over a lifetime, provided the money was invested in qualified retirement plans. The tax would come into effect when the person started drawing his retirement money.

There were some signs that the administration might be softening its opposition to the bill, based primarily on the immediate loss of tax revenue to the government. Administration officials have backed the principle of the measure.

A new proposal was being considered in high quarters that would eliminate one of the arguments raised against the bill—that it did not cover employees of self-employed persons. The proposal would require establishment of retirement plans for such employees if the employer wished to come under the bill's tax deferral program.

The American Medical Association and hundreds of organizations representing small businessmen and other self-employed persons have urged approval of the tax deferral plan. They said it would encourage individual initiative and free enterprise by spurring retirement security similar to that offered in large industries.

MISCELLANY

President Eisenhower vetoed the first major bill of the session—a measure to raise to 900 million dollars the present 10-year ceiling of 500 million dollars on federal spending to curb water pollution. "Because water pollution is a uniquely local blight, primary responsibility for solving the problem rests not with the Federal government but rather . . . state and local governments," said President Eisenhower.

Arthur S. Flemming, Secretary of Health, Education, and Welfare, urged the automobile industry to equip all new cars with a device to reduce fumes but opposed a measure that would make such installation mandatory. "If it has been established that an action can be taken to reduce the menace of air pollution, I think that action should be taken," Flemming told a House commerce subcommittee. Automobile company officials told the subcommittee that the device, which eliminates crankcase gases but not exhaust, could be installed for as little as $10 on new cars.

The U. S. Public Health Service and the American Hospital Association announced formation of a 15-member special committee to develop principles for community-wide health facility planning. The committee, composed of authorities in the hospital and health facility field, will be headed by George Bugbee, President of the Health Information Foundation.

Dr. Arnold B. Kurlander was promoted to the post of assistant surgeon general of the U. S. Public Health Service, a newly established office. Dr. Kurlander will be responsible for providing immediate assistance to the surgeon general on current programs and will also help handle communications between the service's four bureaus and the surgeon general's office. Dr. Kurlander is a native of Cleveland.

Byron E. Harter, administrative assistant since 1950 to Rep. William M. McCullough (R., Ohio), was appointed congressional liaison officer for the Department of Health, Education, and Welfare. He succeeded Robert A. Forsythe, who was named HEW assistant secretary for legislation.

A conference of seven western state officials and officers of the Public Health Service was held in Phoenix, Ariz., to discuss federal enforcement procedures in controlling pollution of interstate waterways. The objective was a thorough study and clean-up of the Colorado River system, which drains about one-twelfth of the land area of the U. S. One of the subjects dealt with was radioactive contamination from uranium milling operations.

A new crackdown on abuse of amphetamines, or "pep pills," is being prepared by HEW. HEW Secretary Flemming said the agency is seeking to have amphetamines placed in the same category as narcotics, which would necessitate the registration of all sales.

RESEARCH IN PREVENTIVE MEDICINE

Thomas Francis Jr., Ann Arbor, Mich.

The aim of preventive medicine is the prevention of disease, and the issue is beclouded when the importance of a disease is measured in terms of the resultant deaths. True prevention includes protection from chemical and physical exposure, correction of dietary deficiencies and excesses, and prevention of infectious diseases. The common assumption that infectious disease has been conquered is false. The Armed Forces Epidemiological Board, established in 1941, with 12 commissions and 180 senior investigators, has been able to make many major contributions. These would scarcely have been possible in other than military populations, but the results have been valuable to the civilian population as well. Research in medicine for the future must be directed toward the prevention of the common annoying chronic diseases.

PREVENTIVE medicine is at present a diffuse term meaning different things to different persons. At times it appears no longer to possess a central theme or phiosophy. A change in name, as some have sugested, would bring little benefit since it might urther obscure the intent. At times the field apears to be interpreted so broadly that care of the ck and disabled—that is, supportive and recontructive medicine—occupies more attention than he primary objective. Of course, all of medicine, nd I mean all sciences contributing to medicine, as a preventive aspect. But the virtue of preventive medicine lies in the concentration of attention n the maintenance of health and the prevention of isease. As Alan Gregg expressed it, "Preventive edicine has the charm and bewilderment and the pportunity of being virtuous, because applying reventive medicine is behaving as we should beave in the light of what we know of the vast apacities of medical science." Perhaps our comlaints that preventive medicine is not fully appreiated tie in with the realization that virtue is not asily maintained and that we think as we live. Our roblems of recruitment may relate to the fact that e spend more time in expounding virtue than in eveloping it.

Concept of Health

Man's progress toward civilization has been losely intertwined with his development of measres to protect life. Some of the adversaries could be recognized even by primitive man, since they related to human behavior and aggression, but disease was understood only as a harmful effect of certain associations revealed by experience. The level of our current knowledge is not much more advanced. Descriptive information has increased

---

Read at the meeting of the American College of Preventive Medicine, Atlantic City, N. J., Oct. 21, 1959, during the tenure of the Third Annual ectureship in Preventive Medicine.

From the Department of Epidemiology and Virus Laboratory, School of Public Health, University of Michigan.

tremendously, but we have gained only a slight foothold in understanding the mechanisms involved in disease processes. The concept of a specific causative factor has been amply demonstrated but constantly challenged in cases in which the etiology of a disorder is yet unproved. We have derived empirical knowledge and procedures with which to limit the incidence or reduce the severity of some disorders, while others increasingly mount the walls of our ignorance. It is obvious that we have more effectively eliminated the buffalo, the whooping crane, and the trailing arbutus than we have obliterated the causes of disease. It is true that some regions of the world are gaining in this struggle; but in other areas unrelieved burdens still exist that constitute continued risks to health and peace in this mobile, shrinking world. Conversely, certain disorders of increasing damage to the longer-lived, more favored populations appear to be diminished by the conditions of life in crowded areas of economic want; this emphasizes the relativity of health, global or individual, and points out that we are scarcely on the threshold of understanding the problems of either health or disease.

Man is, above all, a biological creature living in environments which expose him to an endless array of potentially pathogenic agencies. The effects of some of these are known, but new ones arise as our explorations of the universe enlarge, as we disturb natural adjustments, as we synthesize new products and new conditions of existence, and as we change our way of life. It cannot be expected now or later that a functioning community can be devised which is spared from all harmful exposures—like germ-free animals maintained in stress-proof isolation.

Health, then, may be considered a state of adequate structure and function, with adequate reserves. This state is being constantly bombarded by innumerable potentially pathogenic stresses, so that each person is in a state of potential disorder. The outcome depends on the ability of the person's reserve to absorb the stress without depleting his range of tolerance, or to respond with additions to his reserve to enhance health and resistance to the harmful influence. It is readily apparent that small shocks might be effectively buffered, while excessive insult or continued exposure might well break through. Variation in the threshold of tolerance among individual persons and at different ages is also easily pictured. Conversely, disease is a reaction to a stress which extends beyond the bounds of individual reserve and adaptability. (This can also be applied to a community.) In this sense, we would measure disease or disease potential in terms of health rather than defining health in terms of disease, and our efforts would be directed toward preservation of the norm.

Unfortunately, the available measurements of health are few. Despite bold efforts to proclaim a theme of "positive health," little information regarding the maintenance of health which has not derived from recognition that a certain procedure prevented disease exists today. Consequently, we have no adequate body of measurements of health that are not based on the absence of a disorder. In fact, we describe our present health activities as vaccination against smallpox, use of fluorides against dental caries, or something that is "good" for heart disease. Our current ability to detect and identify disorders depends largely on their severity; what we consider incipient is an already far-advanced biological imbalance. Our so-called health statistics are commonly disease or death statistics. In fact, one of our most disturbing practices is to consider the importance of a disease in terms of resultant deaths as if we were somehow to evite the inevitable. We split life and the family into convenient specialist categories to make the recording of a sequential comprehensive view of the individual person's or group's experience difficult. We witness the tendency to move bithely under the cover of a slogan or in response to the call of the huckster to realms of custodial care or administrative busyness with the end-stages of disorder, while we withdraw from profitable investigation and exploitation in the areas of their causation and prevention. It must be constantly repeated that research is the only hope for the development of preventive medicine—and now I am speaking of preventive medicine literally—namely, prevention of disease. Research offers a new face to the field of practice.

Areas of Preventive Medicine

The areas of true prevention now available may be summarized under three headings.

First, protection from chemical and physical exposure. This applies particularly to occupational health—one of the oldest and a continued area of interest.

Second, prevention by correction of dietary deficiency or excess. This area has a steady range of development as knowledge of the specific significance of various components becomes known and processing changes the character of natural foods.

Third, prevention of infectious disease by specific measures and sanitary social procedures. A limited number of severe, epidemic communicable diseases are effectively prevented by specific vaccination. A few bacterial infections can be prevented by drug or antibiotic therapy, if properly used. Some are limited by sanitary barriers under stable peacetime conditions or by environmental control. Entirely new agents of large epidemic potential are being recognized, and still others can be expected, but none has been eradicated.

Genetics is a field in which knowledge is increasing but which, as yet, is put to limited use in preventive procedures.

The tendency of preventive medicine to move away from unfinished business is nowhere more clearly emphasized than in the field of infectious disease. And nowhere is there a more precarious balance with respect to present preventive procedures. The return of the staphylococcus and other resistant organisms, the development of new antigenic strains, the reliance on sanitary facilities which can be easily disrupted, the ready possibility of importation of infections, the recurrence of epidemics when vaccinations are not thoroughly applied—all emphasize the narrow margin of safety in our safeguards.

The commonly repeated assurance that infectious disease is conquered is simply not in keeping with the evidence. This is emphasized in the compilations of incidence and death presented by Halbert Dunn in "Health and Demography" (1956). Up to 45 years of age, the 12 leading causes of illness are infections, with the exception of accidents, some "functional" digestive disturbances, and some of the disorders of the genital tract and breast in women aged 15-45 years. Beyond the age of 45 years, infection still constitutes a major factor as the immediate cause of illness, although an increasing amount of illness relates to disorders which are referred to as noninfectious.

The United States National Health Survey reports that in the year July 1957-June 1958 45% of all bed-disability days, 36.5% of work-loss days (for persons 17 years and older), and 67% of school-loss days (for persons aged 6 to 16 years) were caused by acute respiratory illness alone. Respiratory disease was responsible for 60 to 66% of the incidence of acute conditions recorded in every age group. In comparison with a total of 764 million days of bed disability caused by all chronic conditions in the United States in one year, there were 593 million from acute respiratory disease alone (see table). The work-loss figures in days for the year were 219 million from respiratory disease and 226 million from circulatory, digestive, and arthritic disease and impairments from injury or other origin combined. The average number of days lost by the usual working population from acute conditions was 5.98 and from all chronic conditions 6.52. These data represent the noninstitutionalized population of the country.

Areas of Research

The examples given clearly present to preventive medicine its continued responsibility in those areas of research dealing with the great body of day-by-day infections which repeatedly interrupt healthy, effective life. They probably are also significant factors in the etiology of other disorders whose origins and causes are as yet poorly defined. In addition, they are leading causes of death during the most vigorous periods of life, from the school years through 44 years of age. The point to emphasize, however, is that research must be increased and maintained in the area of the common, annoying disorders of health, in which the preventive promise is high. Human mortality is still 100%; thus, while death is inescapable, these disturbances can be prevented.

The maintenance of effective health is nowhere in our scheme of life more actively required than in the military services. In the first place, the population involved is selected with care for its healthy status, and if it is to fulfill its functions in training or in operation, those disturbances most commonly disruptive of daily health must be controlled. As would be expected, they comprise primarily the acute diseases of young adult life and accidents. During 1958, the rate of total "excluded-from-duty" admissions to hospitals and quarters in the United States Army was 397 per 1,000 per year. The incidence of acute respiratory infections was 160, representing 46% of all admissions for disease and 40% of all nonbattle causes. Accidents were the next, with a rate of about 53 per 1,000 per year. But, in addition, the recorded incidences of 24 for the class of infective and parasitic diseases, 16 for gastroenteritis, and 15 for urinary and male genital disturbance, rheumatic fever, and others indicate another large group of infectious diseases. With its far-flung geographic dispersions and the increased risks attendant on wartime activities, the military services must also be constantly alert to other common disease problems that are largely avoided at home under conditions of peace and stability. Continued research into etiology, pathogenesis, and prevention of these ordinary diseases is essential, if effective manpower is to be sustained for military operations. It is an old saying that the medical lessons learned in one war are forgotten in the intervals of peace. There has always been a small body of devoted men who have sought to prevent this gap almost by individual effort, just as individual persons or small groups of investigators in civilian agencies have maintained progressive inquiry into specific infectious diseases. But the necessity for coordinated, continuing research which is directed toward prevention of these repetitive and persistent infective urchins has been realistically supported in few quarters.

U. S. Armed Forces Research Commissions

An outstanding example of sustained effort toward understanding and preventing common disorders is the Armed Forces Epidemiological Board. It was established in January, 1941, through the energetic foresight of the late Steve Simmons, chief of preventive medicine, with the aid of the surgeon general of the Army, Magee, and the guidance of the president of the board, Francis Blake, and the administrator, General Bayne Jones. Expansion of the Army had been accompanied, as always, by an increase in the incidence of respiratory disease. The objective, as stated, was "to appoint and maintain a board for the investigation of the etiology, epidemiology, prevention, and treatment of influenza and other acute epidemic diseases in the Army" and to prepare in time of peace for exaggerated risks of wartime mobilization and operation. The organization was to consist of a central board, an additional group of expert scientists who could meet with the board, and investigative teams who could go to military stations for study and control of epidemics. It was emphasized that the organization should be flexible and not hampered by unnecessary administrative delays. The investigative units were termed commissions, and their major focus of concentration was respiratory disease, as evidenced by their names: the commissions on acute respiratory disease, on hemolytic streptococcic infections, on influenza, on mumps and measles, on meningococcic infection, on pneumonia, on cross infections in hospitals, and on epidemiologic survey. In addition, there were commissions on neurotropic virus diseases and on tropical diseases. Their personnel comprised 111 civilian medical scientists who were already engaged in research on these problems.

I recall the extended discussions at the early meetings about whether or not the commissions should serve only as fire-fighting units on call for emergencies in military situations. Although these sporadic excursions could be of aid, the need for continuity in the study of disease problems for fundamental research in microbiology and immunology and for supplementation of military facilities by university and other laboratories was clearly recognized. It was concluded that programs of intensive study must be sustained if the potentialities and the functions of the board were to be effectively met.

The contributions of the board and its commissions during World War II were such as to elicit the signal statement of one judge, that "No one ever got so much, buck for buck, in returns." By attracting and supporting the activities of groups of collaborating specialists, the commissions of the board became focal concentrations of expert knowledge and effective investigation of various diseases on a world-wide scale. It is a pertinent point, however, that it was the common infectious diseases of the area which required the concentrated attention of investigators—whether in the continental United States or in overseas locations.

The normal expectation was that the organization would be disbanded at the end of the war, but the demonstrated value of the commission's approach and the assistance thus available to the U. S. Armed Services was appreciated. It was redesignated the Armed Forces Epidemiological Board, as a Department of Defense agency, to serve the surgeons general of the Army, Navy, and Air Force for consultation on field problems, for field investigations, and for research in preventive medicine. While certain commissions have been discontinued or combined with others, new commissions have been formed, with an epidemiologic orientation toward special and persistent problems of preventive medicine.

At present there are 180 senior investigators officially attached to the board and its 12 commissions. In association with each responsible investigator, several more members of his staff usually participate in the research which the laboratory is pursuing.

Accomplishments of Commissions

I shall not attempt to recount all the accomplishments of the board nor to make expansive claims they are not necessary. What is to be emphasized is that many of these accomplishments would scarcely have been possible had the studies not been made in military populations, with the aid of military scientists and physicians.

In the field of respiratory disease, major contributions in which the commissions have participated include the dynamics of meningococcic herd infections and their chemoprophylaxis; the spread and control of streptococcic infections and their sequelae; the development and application of an effective influenza vaccine, and the establishment of extended listening posts for detection and study of influenza viruses; the epidemiology of atypical pneumonia as a disease of recruits, basic demonstrations of its viral etiology, and later studies of adeno vaccine effectiveness; further field demonstrations of immunization against pneumococcic pneumonia with polysaccharides; the demonstration of new respiratory viruses and their associated clinical reactions; studies toward development of vaccines against measles and mumps; the development of an effective vaccine against Q fever; intensive studies of the ecology and control of infection by Coccidioides immitis; and improvement in smallpox vaccine.

Major contributions have been made to the knowledge of and efforts to control infectious and serum hepatitis; to the identification of dengue and Phlebotomus-transmitted viruses and possible vaccines; and to identification of various encephalitic viruses, their serologic relationships, and vaccine development. Investigations into the principles of natural resistance; into the development, evaluation, and improvement of immunizing procedures; into mechanisms of infection; and into the disease process of such time-honored "old soldiers" as dysentery, typhoid, and cholera, which have not yet faded away, continue. In fact, the entire field of diarrheal diseases is under study, with attention to procurement of better information about the physiological basis of susceptibility and the pathogenic capacity of the agent. Studies of cutaneous disorders—sensitizations, acne, itching, poison ivy, fungal infections, i. e., the ordinary ones—are yielding basic etiological and prophylactic information.

Those studying rickettsial disease represent almost the only remaining nucleus of investigators in the United States, their activities continuing in fundamental research as well as in discovery of improved preventive measures or treatment. Their contributions to the knowledge of the milder form of epidemic typhus or Brill's disease, Tsutsugamushi fever (scrub typhus), and Q fever and to corresponding control measures have been outstanding. Much the same is true of the Commission on Parasitic Diseases with respect to malaria and schistosomiasis; they seek to maintain a corps of competent diagnosticians and scientific experts in the military services especially, but their work turns again to basic research for greater biological information. Studies in environmental hygiene have provided data regarding pollution and the disposal of waste in Arctic areas, adaptation to warm climates, food control, and occupational protection. The influence of low-grade radiation on infection and resistance is being investigated.

The Commission on Accidental Trauma, adapting the epidemiologic approach to an important study of the role of the driver, the machine, and the environmental state has served as a focal point for interested groups who were otherwise isolated. They have had a definite influence on the consideration of safety features and on the search for measures to eliminate the hazardous driver. Although the military importance of accidents, both civilian and military, in motor vehicles is fully demonstrated, there are strong currents of resistance to the serious study of the institution of preventive measures. Nevertheless, the board has taken an important national leadership in creating an effective front of research into the problem of vehicular accidents especially.

One other area of known importance that has been sporadically studied is that of the relation of military housing to infectious and mental disturbances. With every increase in strength of military personnel, platitudinous surveys of the housing problem are made. Each change in barracks is made with little or no advice on the aspects of medical or health engineering. It is obviously a zone for extended study, but fatalism and jurisdictional authority interfere.

The research activities have been financed primarily through U. S. Army medical funds, although the other services have contributed to the support of certain specific investigations. Moreover, extended field studies have been conducted in U. S. Air Force and Navy installations. The individual investigators receive their funds on a contract basis after consideration and recommendation by one of the commissions, approval by the central board, and administrative concurrence by the service. At times, if funds are scarce, additional money may be sought from other agencies for a recommended activity, while affiliations and sponsorship by the commission are retained. The commissions do not propose to act as study sections or as granting agencies or to preempt control of an area of research. Their purpose is to gather into a mutual working relation military and civilian scientists with common interests and the dedication to work toward the solution of a given problem. By close adherence to the preventive medicine divisions of the three services, attention to the military needs can be steadily maintained. Disease situations which require investigation, difficulties in application of recommended measures, and future projections of the work accomplished can be brought forward for consideration by the appropriate commissions. But the areas of study are not laid down purely as military edicts; the scientific approach is largely devised by the scientific judgment of the experts in that field. In effect, each commission constitutes a research institute with a director, even though housed in laboratories of the affiliated investigators, in military installations, or in other institutions which may be sites of study.

Although the orientation is toward military preventive medicine, the entities under study are also the common causes of disability in the civilian population. Consequently, benefits are mutual and those who are benefited are our sons and daughters. Moreover, there is a great conviction among the participants in this work, as scientists and citizens, that the sustained studies are necessary if these problems of preventive medicine in the U. S. Armed Forces are to be met rather than ignored.

Need for Research Commissions in Preventive Medicine

The reason for this expanded discussion of the Armed Forces Epidemiological Board is (1) to emphasize the limited attention now given to coherent study of certain ordinary disorders and (2) simultaneously to point out how an amount of money, small in current terms, but invested in sympathetic support of a sustained united effort, can earn rich dividends. The "commission" plan of investigation recommends itself not merely as a source of expert opinion but as a unit of action research. It should not be an intellectually closed corporation but a collection of balanced judgment and study. It provides the means of encompassing, in a coherent fashion, research on numerous facets of a problem on which information is needed. This information can then be collated, critically evaluated, and projected in an environment of collaborating experts. Dictatorial or financial control of research is avoided by giving the direction of research to the researchers. It retains freedom for individual initiative within a framework of common purpose and objective. In fact, it can often provide support for new adventures which by themselves might wither. Flexibility and versatility permit a change in direction from the concentration on epidemiologic observation to fundamental study of reactions of the host or of the pathogenic agency, as indicated. The commission can provide continuity to research while deriving benefit from new or brief excursions into other areas and can buffer the disturbances of progress occasioned by hucksters and the promoters of expediency. An agency like the Armed Forces Epidemiological Board could well be expanded to deal with other problems and to serve more widely in the national need for research in preventive medicine. It can be a model for advance in difficult and little-understood problems of many kinds. It is my recommendation that, in the planning for future research, serious consideration be given to adoption of the "commission" plan.

Future Tasks for Preventive Medicine

Preventive medicine has long been called the medicine of the future, but what is the future of preventive medicine? I repeat that its future will depend on acceptance, by those who uphold the philosophy of prevention in medicine, of the responsibility for research and the direction it takes and on its willingness to initiate and support vigorous, sustained research in preventive medicine in its literal sense, rather than to leave this to the now-and-then attention of other interests.

A dominant segment of medical research is directed toward the investigation of pathological disturbances which have already become manifest. Clinical attention—and much public health effort—centers on the hope of restoring function or maintaining it at a level that will permit a useful life. Unfortunately, with the exception of certain infectious, toxic, or deficiency diseases, so-called therapeutic procedures do not commonly result in cures, for by the time the manifestations are recognized the defect is well advanced and not ordinarily reversible. This, in general, applies to diabetes, cardiovascular disease, chronic arthritis, cancer, including leukemias, major mental diseases, neurological diseases, pollen sensitizations, and a variety of other disorders. Even with enhanced efforts toward detection of the asymptomatic stages of these disorders, the ultimate result is only slightly influenced.

Progress in our ability to deal with these currently irreversible disorders, or chronic states, calls for increased research, with preventive intent, to study the origins of a disease and the basis of susceptibility to it. It calls for a turn from preautopsy medicine to preclinical medicine. Epidemiologic investigations should be of prime value in identification of susceptible persons and in disclosure of pathogenic factors which convert the susceptible person, the potential case, into a frank case of disease. Beyond this, there is a need to determine the nature of susceptibility, of the defect or injury which depletes the protective reserve, and of the mechanism of the basic injury, to map out the setting. Knowledge should then lead to devising effective procedures of prevention.

Although there are mild stirrings in this direction, preventive medicine is essentially a neglected field. For its fruitful development, active employment of personnel and scientific methodology from all areas of medical science will be needed. In fact, it is an added facet, a necessary supplement to medical research generally. There has been an increase in the wealth of investigative tools with which to reach back into the beginnings of a disorder. But new perspectives, new ideas, and new modes of measurement will be needed. The epidemiologic, clinical, and laboratory disciplines must be merged into an operating philosophy of preventive research. As increased funds have permitted greater freedom of thought and greater boldness in the pursuit of medical research, there has been much wider extension of interest in the origins of these chronic diseases. It probably is evidence also of increasing maturity in research perspectives. Much of this is rising among those engaged in clinical investigation. But my recommendation is that preventive medicine, and especially epidemiology, take a position of forceful leadership in initiation and development in this area. "Grist is ready for the mill, the leaven is active, let's get cooking."

In the September, 1959, issue of the *American Journal of Public Health* there is a series of excellent and frank appraisals of prevention and control of chronic disease. Emphasis is given to the limited facilities now available despite much activity, to the still prevalent emphasis on detection of the disease, to the greater need to understand the problem confronting us, to the need for etiological studies, to the study of susceptible persons, and to a discussion of the information necessary for primary prevention. The total effect is to point out the need for preventive research.

A further and more fundamental product of this research should be the development of adequate standards of health. In seeking information on susceptibility and reserve and protective mechanisms, new biological measurements will have to be developed before early deviations from health and recognition of abnormalities will be detectable. The normal physiological responses to harmful stresses of various kinds will need to be established. The improvement in development and behavior of germ-free animals, despite exposure to varied hazards, is an example of how health may be studied in man. Since much of our present knowledge of health is primitive, the developments in biological science at both the cellular and the molecular level may provide new dimensions for understanding the systemic and "organismal" state. With advancing knowledge a science of health may actually come into being.

This proposal is not intended merely as a declaration of virtuous ideals. Nor would I propose priority for any of the various entities, for in each of the disorders the need for research is great. The determining factor is the imagination and energy of the investigative group. Nevertheless, certain inferences and relationships suggest that atherosclerosis (especially coronary heart disease), diabetes, and rheumatoid arthritis may be more nearly ripe for picking than certain other diseases of a more diversified nature. But cancer and congenital defects are high on the list because of their probable association with infectious agents. It should be emphasized that the field of infection is wide open for study, for there is no adequate information about who, among a group of susceptible persons, will develop frank disease, inapparent infection, or no infection, when all are uniformly exposed, and that prevention of infectious disease is still in its early stages of development.

Report on One Study in Preventive Medicine

The interest evidenced by the School of Public Health at the University of Michigan in the problem of preventive medicine has taken concrete form in the study of one total community—that of Tecumseh, Mich.—with a population of 8,500. The purpose is to study the health and disease and life and death of members of the population in relation to their biological, physical, and social environment. The work was begun as a program undertaken by the faculty of the School of Public Health as a whole, with financial support from the University of Michigan for studies in "human resources." The community was mapped; the population was identified by individual persons, households, and genetic kindreds. Interviews and questionnaires obtained information about any of a series of diseases which the individual subjects and families acknowledged to exist among them. About 50 families gave histories of two or more cases of hypertension or of heart disease, and about 15 told of two cases of diabetes.

Our working hypothesis is as follows: A subject with hypertension or coronary heart disease, for example, serves as an index case. Whether related to environmental exposures encountered in the way or course of life or to genetic factors, the members of the household or of the genetic kindred, or both, are more likely to share those influences than other segments of the population. They are more likely to develop the disorder and hence to provide a focus of susceptible persons. Consistent study of the familial associates should then provide information on susceptibility, the early stages of abnormality, and the course of development of the disease. A developing disease may be observed at different stages in the same unit. Moreover, since persons of all ages are included, observations on contributory factors may be made from early childhood on. That the origins of these diseases go well back into early life seems highly probable. At the kindred level, several generations may be kept under observation. Among those presumed susceptible, pilot studies in the development and evaluation of methods for detection of early aberration can be made. Relationships between the occurrence of different clinical entities can be studied in the same population. The continuing study may also be expected to provide some observations on the incidence of disorders and to suggest features for expanded study in larger populations.

At any rate, with support from the National Heart Institute, examination of the total population has begun, with Dr. Fred Epstein in charge. A comprehensive history, obtained from each family, provides special detail relating to cardiovascular disease, diabetes, arthritis, and chronic pulmonary disease. Each family is then examined clinically—a thorough examination being made, with supportive laboratory studies and again with special emphasis on cardiovascular disease. The population is examined in representative aliquots. In this undertaking we have had the warm support and assistance of the staff of the clinical departments, especially the medical staff, but including surgeons and psychiatrists. A special dental examination is being made of one sample of subjects. Surveys of spastic deformities, fertility, and respiratory disease by family distribution are being made. To date, nearly one-third of the population has had its examination, as requested, with an acceptance of 90 to 92%. The data are being edited and recorded, and certain preliminary measures of uniformity have been made. Although no analyses have been made as yet, it is quite clear that interesting findings will be obtained. With establishment of the prevalence and selective distribution of various diseases by means of a thorough medical history and examination, the identification of the population will have been completed, and the foundations will have been laid for intensive continued study of special segments that harbor a given disorder or groups of diseases.

Summary

New dimensions and postures are recommended for medical research. The guiding concepts should be (1) that research in preventive medicine in the literal sense be forcefully established, strongly supported, and effectively maintained; (2) that research in infectious diseases not be dissipated by deceiving slogans; (3) that research move toward prevention of the so-called chronic diseases whose scope is increasing; and (4) that preventive medicine will be the medicine of the future only if it accepts its proper responsibility, for the future is very near.

Our views of health, and its values, must, like our educational system, reflect our culture and our way of life. They must be projected as the image of our ideals. Freedom and democracy may seem like hollow triumphs if the hopes of life are submerged in a welter of disease. Security and longer life can be miserable acquisitions, if they mean only the continuation of unhealthy states. Preventive medicine can be our most progressive demonstration to all the world of our belief in human life and happiness. Peace, health, and security are of the same fabric. We should weave more of it.

DIABETES MELLITUS IN AN EMPLOYED POPULATION

Sidney Pell, Ph.D.
and
C. A. D'Alonzo, M.D., Wilmington, Del.

Medical information on 90,596 employees of a large company was surveyed during 1956 and 1957 in an appraisal of facts regarding diabetes. The company physicians reported on 408 employees having the disease and an equal number of nondiabetic employees matching the diabetic group as to age, sex, occupation, and location. The incidence of diabetes was 4.5 per 1,000 employees, 4.8 for men (370) and 2.7 for women (38). No significant difference was found in the distribution of ABO blood groups between diabetics and nondiabetics. Although obesity was more common to the diabetics, 92.1% of them had been able to lose weight since the discovery of their diabetes. Hypertension occurred more frequently in the employees with diabetes, especially those overweight, but obesity could not be singled out as the main cause of the hypertension.

Series of cases for diabetic studies are usually drawn from clinics or hospitals; less frequently from the population at large. Generalizations of findings from the former sources are somewhat limited because their patients tend to represent specific ethnic and socioeconomic groups, and the treatment they receive is standardized in accordance with the general philosophy of diabetic management adopted by the physician in charge. Population studies have the advantage of encompassing a wider representation of the diabetic population, but they also have the disadvantages of being costly and lacking in extensive and detailed medical histories.

The diabetics who comprise the subject matter of this paper are employees of E. I. du Pont de Nemours & Company. One might consider them a sample of a third group available for study; that is, the employed diabetic. Although our diabetics are a select group, in that they may be healthier and better controlled than diabetics in general, they are a fruitful source of material for several reasons. First, they provide an opportunity to study the effect of the disease on their status as employees. Second, the patients come from all parts of the country. Third, they represent a large variety of occupations and a wide range of economic levels. Fourth, many clinical and laboratory data are available from records of periodic health examinations. And, finally, it is a simple matter to obtain a randomly drawn control group, matched to the diabetics by age, sex, occupation, and geographical area.

The findings reported here deal with the prevalence of diabetes in the company, variations in prevalence by job levels, the relation of the disease to ABO blood groups, and an analysis of the occurrence of complications and associated diseases. Articles concerning genetic factors and the experience of our diabetics with respect to sickness, absenteeism, and frequency of injuries will be published in subsequent papers.

Source of Material and Survey Procedures

Company Medical Facilities, Policies, and Records.—During the past 25 years, it has been the practice of the company to provide an extensive periodic physical examination to all employees. These examinations are given, in almost all instances, by company physicians. The laboratory tests include hemoglobin determinations, whit blood cell counts, and urinalyses to test for th presence of sugar and albumin. More intensiv blood and urine studies are performed when indicated by laboratory findings and history. The routine examination also includes a chest x-ray and for employees past 35 years of age, at least on electrocardiogram.

Almost all employees have been receiving thei medical examinations once a year, but many ar seen more frequently for consultations and specia examinations to detect early any possible advers effects of potential occupational hazards, as part o our preventive medical program. In addition, production employees who are absent for reason o illness or injury must report to the plant medica unit for evaluation on their return to work.

When an employee exhibits abnormal condition that require treatment or further diagnostic measures, he is referred to his family physician or specialist. Contact between the company and th local medical community is maintained, to follow the progress of patients. This contact is also o value in the administration of the company sicknes benefit plans, which require the attending physician to certify the fact and cause of disability.

Biostatistician (Dr. Pell) and Assistant Medical Director, Medical Division (Dr. D'Alonzo), E. I. du Pont de Nemours and Company, Inc.

Employees with glycosuria are given blood sugar (usually postprandial) or glucose-tolerance tests. Most company installations have facilities to administer these tests, but those which do not have the work done at a local laboratory. Some company physicians have blood sugar determinations made when there is a family history of diabetes without glycosuria. All employees suspected of having diabetes are examined closely until a diagnosis of diabetes is clearly established or eliminated.

The company does not, as a matter of policy, refuse employment to anyone because of diabetes mellitus, except when the applicant cannot demonstrate that he is able to control the disease. The suggested policy and procedure for company physicians is stated as follows: "Uncontrolled diabetes is a severe hazard. These cases should not be accepted, under any circumstances, until the blood sugar is within normal limits and medically controlled. If the applicant is accepted, he should be followed up every three months or so, or at least until the examiner satisfies himself that the diabetes is well managed."[1] Diabetic employees are encouraged to seek the help and advice of their personal physicians and their company physicians for problems concerning the management of their diabetes in relation to their job.

PHYSICIAN'S QUESTIONNAIRE

DATE ____ DEPARTMENT ____

LOCATION ____

1. Name of Employee ____

2. Occupation (describe fully) ____

3. Is employee's occupation restricted because of diabetes? ____Yes ____No

4. Marital Status: M S W D Sep. No. children ____

5. Age at Onset of Diabetes ____

6. How many times during the past year has the employee seen a physician for the care of his diabetes? ____

7. Current Insulin Requirements: ____None

Kind	Number of Units Per Day	Check When Given								
		Breakfast			Lunch			Dinner		
		Before	During	After	Before	During	After	Before	During	After
Regular										
Protamine										
NPH										
Globin										
Lente										
Total										

8. Has the employee taken any of the new anti-diabetic drugs? ____Yes ____No

If yes, a) Which one? ____
b) How many tablets per day? ____
c) Are they being taken now? ____Yes ____No
d) For what period of time were they taken? ____
e) How effective were the tablets in reducing insulin requirements? ____

- 2 -

9. Current Diet Restrictions: ____None

	No. Grams Per Day
Carbohydrates	
Proteins	
Fats	

Other Diet Restrictions:

10. How many times during the past year has the employee, to his knowledge, been in shock, acidosis, or coma; and, prior to last year, what was the average number of times these occurred per year since the onset of diabetes?

	Number	
	Past Year	Average Prior Years

Questionnaire distributed to company physicians for assistance in interviewing diabetics.

Survey Procedures.—Our survey was begun in June, 1956. At that time, we distributed questionnaires (see figure) to all company physicians and asked them to complete the questionnaire by interviewing every diabetic in their plant. Thus, the company physician was given the responsibility of identifying the diabetic. Since each doctor is assigned about 1,000 employees, the names of the few diabetics seen by them could easily be recalled or obtained from their medical records. Nevertheless, we allowed a little more than a year to elapse for the completion of the questionnaire. During that time, each physician examined all of his patients at least once and was in a position to identify diabetics not recalled by him at the start of the survey.

The choice of diagnostic criteria was left, of course, to the judgment of the employee's personal physician. In questionable cases, we recommended to the company physician that, for purposes of this study, a diagnosis of diabetes be made when the blood sugar level exceeded 170 mg. per 100 cc. in one-half to one hour after the ingestion of a test meal (or a meal high in carbohydrates) or when the blood sugar level did not return to a level below 150 mg. per 100 cc. two hours after the meal, or both of these conditions obtained. Of course, no set of criteria will prevent false-negative and false-positive diagnoses. In our company, however, these risks are reduced because of the repeated health examinations and close follow-up of patients with borderline and indeterminate cases.

After obtaining the names of all the known diabetics in the company, we selected a control employee, matched to each diabetic by age (five-year categories), sex, occupation (i. e., production or salaried), and location. The controls were selected by means of random numbers from a complete listing of company employees. We then requested the medical records of the diabetics and controls to make abstracts of information pertinent to our study.

Prevalence of Diabetes

Variation by Age and Sex.—During the one-year period in which the survey was conducted (June, 1956, to June, 1957), company physicians reported 408 patients with diabetes among the company's 90,596 employees, a prevalence rate of 4.5 per 1,000 persons. Among these were 370 men and 38 women. Prevalence rates by age and sex, shown in table 1, indicate the well-known increase in prevalence with age.

TABLE 1.—*Prevalence of Diabetes Mellitus by Age and Sex**

	All Employees		Men		Women	
Age, Yr.	No.	Rate	No.	Rate	No.	Rate
<20	1	1.3	1	2.8	0	0
20-24	1	0.1	0	0	1	0.4
25-29	8	0.6	8	0.7	0	0
30-34	29	1.9	26	2.0	3	1.3
35-39	50	3.4	47	3.7	3	1.5
40-44	56	4.3	52	4.6	4	2.7
45-49	54	5.1	50	5.3	4	3.1
50-54	76	10.2	68	10.3	8	9.4
55-59	68	14.7	60	14.5	8	15.7
60-64	65	21.3	58	21.0	7	23.8
Total	408	4.5	370	4.8	38	2.7

* Rates per 1,000.

Comparisons with Other Surveys.—The actual number of diabetics in the United States has been a matter of speculation for many years. The National Health Survey of 1935-1936[2] obtained a prevalence rate of 3.7 per 1,000 by means of household interviews. That this figure is a gross underestimate of the actual prevalence of diabetes has been strongly suggested by more recent population surveys in which blood sugar tests have been used as a basis for the identification of diabetics. In Oxford, Mass., the prevalence rate was found to be 20 per 1,000,[3] and in three communities in Ontario, Canada, 12.9 per 1,000.[4] Among industrial surveys, prevalence rates per 1,000 were reported as 5.5 by Hemmett,[5] 13.0 by Wade,[6] and 16.0 by Canelo and others.[7]

If the screening surveys that have been cited come closest to estimating the actual prevalence of diabetes in the general population, the observed rate in our company, 4.5 per 1,000, must be considered low. Two possible explanations for the difference are as follows.

Screening Methods.—Most company medical units rely only on the presence of glycosuria as a means of identifying potential diabetics. Wilkerson and co-workers[8] demonstrated that urine tests alone are nonspecific and insensitive for screening purposes. Although the annual repetition of urinalyses done on company employees increases the chances of detecting diabetes, it is possible that some mild cases remain unidentified.

Selectivity of Company Population.—As stated earlier, company policy does not favor the employment of severe uncontrolled diabetics. In addition to this group, there may be other diabetics who do not enter the company population. These may include diabetics with disabling complications, or those, who, because of their condition, do not seek employment with the company.

Variation in Prevalence by Job Level

Male employees were divided into five broad occupational categories. One category consists of production workers; that is, craftsmen, operatives, and other employees engaged in various types of skilled, semiskilled, and unskilled manual labor. This group comprises about two-thirds of the male population in the company. The other four categories consist of salaried employees grouped according to their income level. The highest group is made up of persons in managerial and executive positions, while the other levels include supervisory, professional, technical, and clerical personnel.

Age-adjusted prevalence rates in each of the five categories are shown in table 2. Differences among these rates are significant ($0.05 > p > 0.02$). Among the four salaried groups, there can be seen an inverse relationship between job level and prevalence of diabetes. This association may be due to a selective mechanism, by which diabetics may have, for various reasons, less chance than nondiabetics for promotion to supervisory and managerial positions.

The prevalence rate among production employees is lower than that found in the two lower categories of salaried employees. Part of this difference may be explained by the sedentary nature of the work done by salaried personnel or, conversely, the protective effect of the physical activity of production workers. Another factor may be a tendency of some diabetics to move or keep away from occupations in production areas because of the demands of shift work.

TABLE 2.—*Age-Adjusted Prevalence Rates of Diabetes Mellitus Among Men, by Job Level*

Job Level	Employee Population	Diabetics, No.	Age-adjusted Rate per 1,000
Salaried: lowest	5,072	31	6.3
Salaried: lower middle	10,014	51	5.6
Production	51,279	233	4.7
Salaried: upper middle	9,118	49	4.6
Salaried: highest	970	6	3.5
Total	76,153	370	4.8

It is interesting that the pattern of occupational variation in prevalence of diabetes, described above, is similar to the pattern we found in studying the incidence of acute myocardial infarction. The rankings of the five job categories were identical in the two studies. It is possible that the incidence or prevalence of other forms of chronic disease may yield similar occupational differences and that the same factors may be operating to produce them.

Use of Orally Given Hypoglycemic Agents

During the one-year period of our survey, only nine patients reported the use of orally given drugs to control the blood sugar level. Five of these patients, who normally require a daily insulin dosage of 26 units or more, had to resume taking insulin because the drugs were not effective. The drugs appeared to be successful for the other four diabetics, but three of them had never taken insulin, and the other had taken only 15 units per day.

Blood Types

Some company installations include blood typing as a part of the preemployment medical examination. Among the subjects in this study, we were able to obtain the ABO blood groupings of 265 diabetics and 275 controls (table 3). Differences in the frequency distributions of the blood types between the diabetics and controls are small and can easily be attributed to sampling variation ($p > 0.50$). Our findings are not in agreement with those of McConnell and associates,[10] who reported an increased frequency of persons with group A and a decreased frequency of those with group O blood among 1,333 diabetics who were compared to controls.

Overweight and Hypertension

Criteria.—To classify our subjects according to the presence or absence of overweight and hypertension, we used, for this and other studies we are undertaking, the following criteria.

A person was classified as overweight if his body weight, as measured during his latest periodic health examination, exceeded his ideal weight by 20% or more. We specified a person's ideal weight as the weight midway between the allowable extremes for a person of medium frame, as recommended in the height-and-weight tables of the Metropolitan Life Insurance Company.

TABLE 3.—*Distribution of Blood Types Among Diabetics and Controls*

Blood Type	Diabetics No.	Diabetics %	Controls No.	Controls %
O	131	49.4	132	48.0
A	93	35.1	102	37.1
B	27	10.2	32	11.6
AB	14	5.3	9	3.3
Subtotal	265		275

Total	408	100.0	408	100.0

A classification of hypertension was made on the basis of blood pressure readings that were taken during the past 10 years at the time of the employee's periodic health examination. He was designated as hypertensive if his records showed two successive annual readings of 150 mm. Hg or more systolic or 94 mm. Hg or more diastolic.

Frequency of Occurrence.—Excess weight in diabetics is a common clinical finding, and its positive role in the etiology of the disease is well known. In our series, 36.0% of the diabetics are currently overweight, but, of 349 diabetics for whom information is available, 164, or 47.0%, were overweight at the time of onset of the diabetes. These figures are contrasted to 27.4%, the proportion of the controls who are overweight at the present time. The success of our overweight diabetics in losing weight is indicated by the fact that, of the 164 diabetics who were overweight at onset, 151, or 92.1%, have shown a net loss in weight since that time.

TABLE 4.—*Prevalence of Hypertension Among Diabetics and Controls by Percentage Overweight*

Weight Variation, %	Diabetics Total, No.	Diabetics Hypertensives No	Diabetics Hypertensives %	Controls Total, No.	Controls Hypertensives No.	Controls Hypertensives %

Unknown	3	1		2	0	
Grand Total	408	63	15.4	408	44	10.8

Several investigators [11] have reported that hypertension occurs more frequently in diabetics than in nondiabetics. Munro and colleagues [11b] found the difference to be much more pronounced in women than in men. According to our criteria, described above, hypertension is present in 63 diabetics and 44 controls, or 15.4% and 10.8%, respectively, of the total in each group ($p = 0.06$). Overweight and hypertension occur jointly in 9.6% of the diabetics and 4.7% of the controls; that is, about twice as frequently in the diabetic group ($p < 0.01$).

Since overweight is more common among diabetics than nondiabetics, and since there is a positive association between overweight and hypertension, one might suspect that the higher frequency of hypertension among diabetics might be due to the higher frequency of overweight among them. Our data, however, indicate that the excess of hypertension among diabetics cannot be attributed to excess body weight alone. As seen in table 4, the greater prevalence of hypertension among diabetics occurs in each of the three highest categories of overweight. Data obtained by Munro and colleagues [11b] led them to the same conclusion.

Relation to Severity of Diabetes.—The prevalence of hypertension by daily insulin dosage, as shown in table 5, indicates an inverse association between these two variables. Of 236 diabetics who take no insulin or less than 20 units per day, 48, or about

20%, are hypertensive. The prevalence of hypertension decreases in each successive category of daily insulin dosage. Among the most severe cases, that is, in patients requiring 50 or more units per day, hypertension is present in only 3 of 52 diabetics, or 5.8%. Although the number of hypertensives in each category is small, the probability that the differences among the prevalence rates will occur by chance alone is about 0.02.

Table 5.—*Prevalence of Hypertension by Daily Insulin Dosage*

Daily Insulin Dosage, Units	Total	Hypertensive	
		No.	%
None	194	38	19.6
1-19	43	10	23.3
20-29	39	5	12.8
30-49	78	7	9.0
>49	52	3	5.8
Total	406	63	15.4

To explore this matter further, we compared the prevalence of hypertension among diabetics with that of the controls by the presence or absence of overweight and divided the diabetics into two groups: those who took no insulin or less than 20 units per day (mild cases) and those who took 20 or more units per day (moderate and severe cases).

The data, presented in table 6, show no significant differences in prevalence of hypertension between controls and moderate and severe diabetics. This is true for persons who are overweight as well as those who are not overweight. Among persons who are not overweight, there are no significant differences in prevalence of hypertension among mild diabetics, moderate and severe diabetics, and nondiabetic controls.

Among overweight persons, however, the prevalence of hypertension is significantly greater among the mild diabetics than it is among the moderate and severe diabetics and the controls ($p<0.05$). Among the 110 overweight diabetics with mild disease, hypertension is present in 30.9%. This is contrasted to 13.9% in the moderate and severe group and 17.1% in the control group.

Table 6.—*Prevalence of Hypertension by Presence or Absence of Overweight Among Controls and Among Diabetics According to Daily Insulin Dosage*

	Mild Diabetics—No Insulin or Less than 20 Units			Moderate and Severe Diabetics—20 or more Units			Controls		
		Hypertensive			Hypertensive			Hypertensive	
	Total	No.	%	Total	No.	%	Total	No.	%
Not overweight	126	13	10.3	133	10	7.5	295	25	8.5
Overweight	110	34	30.9	36	5	13.9	111	19	17.1
Total	236	47	19.9	169	15	8.9	406	44	10.8

Thus, the higher rate of hypertension found in our series of diabetics, when compared to the controls, is concentrated in the overweight patients with mild cases.

Diseases Associated with Diabetes

Table 7 shows the frequency with which the occurrence of certain diseases was noted in the medical records of the diabetics and controls. In assessing the differences between the two groups, consideration should be given to these factors. First, for some diseases listed there are not a sufficient number of cases with which to obtain a reliable estimate of the true difference between the two groups. Second, some of the diseases may be present but not diagnosed, and, if diagnosed, inadvertently omitted from the medical record. Third, diabetics are seen by physicians more frequently than are nondiabetics; hence, the presence of a disease is more likely to be detected earlier in a diabetic than in a nondiabetic. The biases just mentioned are probably minimized in our series because of the thoroughness of the periodic health examination provided by the company to both diabetics and nondiabetics.

Table 7.—*History of Certain Diseases Among Diabetics and Controls*

	Diabetics		Controls		
	No.	%	No.	%	p*
Hypertension	63	15.4	44	10.8	.06
Coronary artery disease	32	7.8	11	2.7	<.01
Skin disease	30	7.4	20	4.9	>.10
Gallbladder disease	20	4.9	8	2.0	<.05
Peripheral vascular disease	11	2.7	2	0.5	<.05
Retinitis	10	2.5	0	0	<.01
Neuropathy	9	2.2	5	1.2	>.30
Cataracts	5	1.2	8	2.0	>.50
Thyroid disturbance	8	2.0	9	2.2	>.20
Peptic ulcer	12	2.9	24	5.9	<.05

* Probability of difference between diabetics and controls occurring by chance alone.

A higher prevalence rate among diabetics, greater than would be expected by chance alone ($p<0.05$), was found to occur in the cases of coronary artery disease, gallbladder disease, peripheral vascular disease, and retinitis. The proneness of diabetics to develop these diseases is well known. Skin diseases were also more common among the diabetics than the nondiabetics in our study, but the difference in prevalence rates is not great enough to exclude the possibility that it arose by chance alone. Data on neuropathies, cataracts, and thyroid diseases are too fragmentary to draw inferences from them. The relation of hypertension to diabetes was discussed in the preceding section.

Of particular interest is the more frequent occurrence of peptic ulceration among the nondiabetics; i. e., 5.9% compared to 2.9% in the diabetic group ($p<0.05$). This is consistent with the findings of other studies. Rothenberg and Teicher[12] reported peptic ulcer in 0.25% of 3,525 diabetics compared to 1.49% of 130,500 total hospital admissions. At the Mayo Clinic,[13] peptic ulcer was found in 2.3% of 2,584 diabetics and in 3.7% of the total number of admissions. One might suspect that age differences between the diabetics and nondiabetics in these studies might account for the lower prevalence of peptic ulceration among the diabetics, because diabetes is prevalent in older persons and peptic ulcer in younger persons. In our study, however, the nondiabetic controls were matched to the diabetics by age, so that this factor cannot explain the difference we observed.

Comment

That some relationship exists between the pituitary gland and diabetes mellitus has been well established by the work of Houssay.[14] He demonstrated experimentally a marked reduction of the severity of diabetes in animals by removal of the anterior pituitary gland, and, conversely, the production of diabetic symptoms by the administration of anterior pituitary extract. Clinical indications of this relationship are the rapid growth and early maturity of diabetic children and the occurrence of glycosuria in such conditions as pregnancy, basophilic adenomas of the pituitary gland, and as a sequela in the clinical use of ACTH.

Since hormones are implicated in the etiology of diabetes mellitus, it is possible that hormonal disturbances may play a part in the development of certain "stress diseases" among diabetics. In our series of cases, the prevalence of essential hypertension, commonly regarded as a stress disease, was found to be excessively high among the overweight diabetics with mild disease and inversely related to insulin dosage. These findings bring to mind certain interesting speculations. For example, does insulin, itself have a blocking, inhibitory, or neutralizing effect on the pituitary-adrenal axis? One might also consider, in this regard, the homeostatic action of insulin and epinephrine in the maintenance of normal blood sugar levels. A high intake of insulin may be accompanied by a reduced output of epinephrine, thus tending to lower blood pressure levels, whereas the diabetics who take little or no insulin may have a relatively high output of epinephrine, and, consequently, higher blood pressures.

Although stress may be involved as a component in the etiology of such conditions as obesity, hypertension, atherosclerosis, and cholelithiasis, the excess prevalence of these diseases among diabetics may be due, partly or wholly, to the derangement of carbohydrate and lipid metabolism characteristic of diabetes.

Peptic ulcer is the one stress disease which has been found to be less common among diabetics than nondiabetics. This is not consistent with the idea that diabetes and complicating stress diseases have a common origin in the stress mechanism, but there are possible explanations for this apparent contradiction. First, the body's response to stress is not necessarily mediated through the gastric area, but may operate via the pancreatic-adrenal route alone or through more than one pathway. Second, Clarke[15] has suggested that the amount of secretion of hydrochloric acid may be determined by a genetic factor transmitted with the ABO blood type, O leading to hyperchlorhydria and A to achlorhydria. In support of this view, he cited the increased frequency of type O blood among persons who have peptic ulcer, which is associated with hyperchlorhydria, and the excess of type A among persons with gastric carcinoma and pernicious anemia, diseases associated with achlorhydria. He then cited a study by McConnell which showed increased frequency of group A among young diabetics, pointing out that in persons with diabetes mellitus duodenal ulcer is rare and achlorhydria common. Thus, under Clarke's hypothesis, the decreased prevalence of peptic ulcer among diabetics would be due to the protection afforded by a genetically transmitted achlorhydria.

Summary

A survey of diabetics employed by E. I. du Pont de Nemours & Company revealed 408 cases, a prevalence rate of 4.5 per 1,000 persons. Among salaried employees, prevalence was inversely related to job level. The disease was found to be less prevalent among production workers than among the lower level salaried employees. No significant difference was found in the distribution of ABO blood groups between the diabetics and the controls. Overweight was found to be more prevalent among the diabetics than the controls, but 92.1% of the diabetics who were overweight at the time of onset have shown a net loss in weight since that time. Hypertension was more common among the diabetics than the controls, but the excess was found to be concentrated in the overweight patients with mild cases. The higher prevalence of hypertension among the diabetics was not due to the higher prevalence of overweight among them.

The prevalence of hypertension was inversely related to daily insulin dosage. There are possible explanations for this relationship. The prevalence of coronary artery disease, gallbladder disease, peripheral vascular disease, and retinitis was significantly greater among the diabetics than the controls. The proneness of diabetics to these diseases has been generally accepted on the basis of several postmortem studies, clinical observations, and the relation of these diseases to the pathology of diabetes. A history of peptic ulcer was significantly more common among the nondiabetic controls than the diabetics, confirming the findings of other studies.

Dr. A. J. Fleming and Mrs. Sara M. Rodgers assisted in the preparation of this study.

NONUNION OF THE CLAVICLE

Charles S. Neer II, M.D., New York

Ununited fractures of the clavicle are rare, and when nonunion occurs the cause should be found. Of 18 cases of nonunion here studied, 4 were in the lateral third of the bone, and nonunion was explained by the rupture of the coracoclavicular ligament. When this ligament is intact, union is generally prompt. The other 14 were in the middle third of the bone, and in 10 of these nonunion was ascribed to local tissue damage, stripping of soft parts, loss of valuable bone, inadequate internal fixation, and infection connected with the initial treatment by open operation. Surgical correction of fractures of the middle third must be done with due regard to fixation and with minimal damage to soft parts. Fractures of the lateral third, if complicated by disruption of the acromioclavicular ligament, are best treated by internal fixation.

The clavicle, as a bone, is a nonconformist. It is the first to ossify in the embryo, and it continues throughout life to enjoy a remarkable reputation for its ability to form bone and heal. One of every 20 fractures[1] occurs in the clavicle, and yet failure of union has rarely been recognized. Nevertheless, during the past year, five patients with ununited fractures of this "invincible bone" were seen at the New York Orthopaedic-Columbia-Presbyterian Medical Center. It has recently been suggested[2] that the incidence of this complication is rising. These facts prompted a study of the causal factors, pathology, and treatment of this condition.

Materials and Methods

Table 1 shows an analysis of 18 ununited fractures of the clavicle in patients treated by our service between the years 1936 and 1959. Patients with pseudarthroses secondary to neoplastic, congenital, or metabolic processes were excluded; only those with traumatic lesions were considered. Two with acute fractures that had been initially excised were omitted because both the cause and the pathological findings were atypical. Three children with ununited clavicles were thought to have complications of birth fractures rather than failure of development.[3] They were excluded from the series; how-

---

Read before the Section on Orthopedic Surgery at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 10, 1959.

ever, they are of interest and will be described briefly later. With the exception of case 18, the progress of these patients was followed clinically and roentgenologically for a minimum of 6 months, with an average follow-up period of 20 months.

Cause.—Lesions of the middle and outer thirds should be considered separately. No ununited fractures of the inner third were seen. All four of the patients with pseudarthroses in the outer third also had tears of the coracoclavicular ligaments (fig. 1). When these ligaments were intact, prompt union was the rule. When they were disrupted, delayed union or nonunion followed, unless the fracture was stabilized by internal fixation. The ligamentous disruption must be looked on as the factor responsible for nonunion in the outer third.

Fractures are more common in the middle third (67%), and, as expected, most complications, including nonunion, occurred in patients with fractures in this region. Of the 14 patients with ununited midclavicular lesions in this series, 10 had been treated initially by open operation (table 2). It is interesting that of 2,235 patients with middle-third fractures treated by closed methods in our clinic, only 3 (0.1%) had failure of union. On the other hand, of 45 patients treated by immediate open reduction, 2 (4.6%) had failure of bone union. These facts indicate that the most important causal factor in nonunion of fractures of the middle third has been improper open surgery. Local tissue damage, soft part stripping, removal of valuable bone, inadequate internal fixation, and infection were frequent features of these operative procedures. Local tissue damage had often been augmented by a severe initial injury. Other causal factors included inadequate immobilization of the unconscious patient and, in two instances, rotation of the intermediate fragment, with interposition of

TABLE 1.—*Analysis of Eighteen Patients with Nonunion of Clavicle*

Case No.	Year	Patient Data*	Injury: Condition	Injury: Type and Duration	Injury: Cause	Injury: Symptoms	Initial Treatment	Repair	Result
1	1936	M, 20, truck-driver	3rd refracture	Type 1, right one-third, 4 yr	Underdeveloped clavicle	Deformity	Closed	Refused	Full heavy use, no pain
2	1940	M, 23, laborer	Accident while intoxicated	Type 1, broken wire, middle one-third, right, 2 yr	Operation	None	Open	Refused	Full heavy use, no pain
3	1940	M, 49, steel worker	Hit by 400-lb. beam	Type 1, left middle one-third, 3 yr	Severe injury, operation	Pain, weakness	Open	Tibial graft, IM rod, wire loop, spica	Good
4	1941	M, 22, roofer	14-ft. fall	Type 1, left middle one-third, 11 mo.	Severe injury, rotated fragment	Pain	Closed	Local chips, IM rod, wire loop, spica	Good
5	1945	M, 17, student	Automobile accident	Type 2, ossified ligaments, outer left one-third, 10 mo.	Torn coraco-clavicular	Pain	Closed	Local chips, plate, spica	Good

10	1951	F, 30, housewife	Fall	Type 1, broken wire, left middle one-third, 11 yr.	Operation	Deformity, weakness	Open	Removal of bone prominence and wire	Poor
11	1954	F, 58, housewife	20-ft. fall	Type 1, ossified ligaments, left outer one-third, 2 yr.	Torn coraco-clavicular	Pain, fatigue	None, multiple injuries	Refused	Persistent symptoms
12	1956	F, 18, student	Surgical approach	Type 2, resorption, right middle one-third, 3 yr.	Operation	Deformity, fatigue	Open	Tibial graft, IM rod, spica	Poor
13	1957	M, 40, executive	Surgical approach	Type 2, infection, resorption, right middle one-third, 18 mo.	Operation	Pain	Open	Tibial graft, screws, rod, loop, spica	Poor
14	1958	F, 35, housewife	Fall	Type 2, resorption, left middle one-third, 13 mo.	Operation, infection	Pain	Open	Iliac graft, IM rod, spica	Poor
15	1958	M, 58, taxicab driver	Automobile accident	Type 1, right middle one-third, 9 mo.	Severe trauma, rotated fragment, coma	Click, weakness	None, multiple injuries	Refused	Full use as cabdriver
16	1958	F, 50, housewife	Fall from horse	Type 2, resorption, right middle one-third, 1 yr.	Operation, infection	Pain, deformity	Open	Iliac graft, IM rod, loop, spica	Good
17	1958	M, 33, executive	Fall from horse	Type 1, ossified ligaments, right outer one-third, 10 mo.	Torn coraco-clavicular ligaments	Tenderness, occasional pain	Closed	Refused	Pain with tennis and golf
18	1959	F, 44, housewife	Automobile accident	Type 2, right middle one-third, 8 mo.	Operation	Pain	Open	Frozen homoplastic graft, IM rod, spica	Inadequate follow-up examination

* Sex, age, and occupation.

Nonunion of the Clavicle in Children.—Defects in children should be considered separately, because it is impossible to differentiate positively between congenital pseudarthrosis due to failure of development and traumatic defect. Three children under 12 years of age were seen who were thought to have ununited birth fractures. In each, the lesion was unilateral and had been noted for the first time when the child was 2 to 3 months of age, and the "tumor" increased in size as the child grew older. Roentgenography indicated middle third defects with ample bone substance and a false joint (fig. 7). There were no associated congenital anomalies elsewhere in the body. Repair was easily accomplished because there was adequate length. The embryologist[6] and radiologist[7] at our center believed that these lesions had the characteristics of ununited fractures rather than developmental defects. It therefore seems probable that they should be differentiated from neurofibromatosis or failure of development, especially because their prognosis after repair is so much better.

Comment

Open reduction and internal fixation constitute the preferred procedure in a few specific patients with clavicular fractures, e. g., those with fractures of the outer third associated with tears of the coracoclavicular ligaments, middle third fractures with rotation of a large intermediate fragment, soft tissue interposition, or vascular or brachial plexus compression. Operative treatment may also be necessary for immobilization in certain patients with

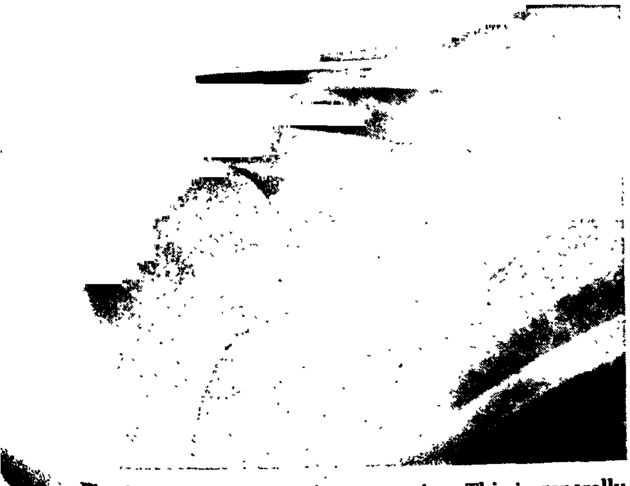

Fig. 6.—Repair of outer [illegible] nonunion. This is generally accomplished by [illegible] bone union.

Summary and Conclusions

A series of 18 patients with ununited fractures of the clavicle is presented. Four fractures were in the outer third and 14 were in the middle third. The clavicle is not "invincible." Lack of immobilization, as in comatose patients, may result in nonunion. Delayed union or nonunion of fractures of the outer third is produced by the instability associated with tears of the coracoclavicular ligaments. Outer third fractures with concomitant ligamentous disruption are best treated by internal fixation, in distinction to fractures in which the ligaments are intact. By far the most frequent cause of nonunion of fractures in the middle third has been improper initial operation. Operation here must be done with the same regard for soft part attachments and fixation as in other open reductions.

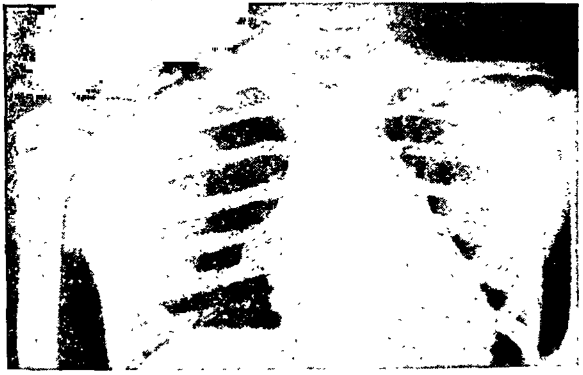

Fig. 7.—Probable nonunion of birth fracture. Although it is impossible to differentiate this from pseudarthrosis due to defective development, it seems probable that certain of these lesions, such as one shown, are actually ununited birth fractures.

Nonunion of the clavicle usually produces sufficient deformity and symptoms to require treatment. Treatment should consist of the reestablishment of bone continuity rather than excision, except when the lesion is producing pressure on the brachial plexus or subclavian vessels or in pathological fractures in patients whose life expectancy is limited. Bone union is more apt to occur if end-to-end contact of the fragments is maintained rather than the gaps bridged with bone grafts.

POSTPARTUM HYPERTENSION AFTER USE OF VASOCONSTRICTOR AND OXYTOCIC DRUGS

ETIOLOGY, INCIDENCE, COMPLICATIONS, AND TREATMENT

Gilbert N. Casady, M.D., Daniel C. Moore, M.D.
and
L. Donald Bridenbaugh, M.D., Seattle

In a study of 8,000 deliveries performed under continuous caudal block analgesia, the records of 741 women indicated that the combined effect of a vasoconstrictor and an oxytocic drug, given three to six hours apart, led to severe hypertension in 34 (4.6% of 741) patients. These findings suggest that the patient's need for prophylactic administration of vasoconstrictor drugs in conjunction with caudal block analgesia in obstetrics should be evaluated before giving them. Treatment with chlorpromazine hydrochloride, to prevent the severe and disabling complications of postpartum hypertension, is essential.

Because of the many advantages for both the mother and the baby, the number of deliveries performed each year with use of subarachnoid (spinal) block, caudal block, epidural block, and pudendal block anesthesias is steadily increasing. When a subarachnoid, caudal, or epidural block is administered, vasoconstrictor drugs may be used intravenously or intramuscularly to prevent or correct a precipitous fall in blood pressure. If local infiltration of the perineum or pudendal block is used, the local anesthetic solution often contains a vasoconstrictor drug to prolong analgesia and prevent rapid absorption of the local anesthetic agent. During or immediately after the delivery of a baby, it is not unusual for an oxytocic drug to be given.

Too few physicians are aware that a severe, persistent, dangerous hypertension and even rupture of a cerebral blood vessel which may cause brain damage and hemiplegia can result from the combined effect of a vasoconstrictor and an oxytocic drug which have been administered to a patient within three to six hours of one another. Further study of this problem was prompted by the admission on Nov. 8, 1957, of a patient who had sustained a subarachnoid hemorrhage due to rupture f an intracranial aneurysm within two hours after ivery. The patient had received a caudal block; the caudal block was initiated, a vasocon- drug was administered prophylactically intramuscularly to prevent any fall in blood pressure. An oxytocic agent was administered at the time of placental delivery.

Method of Study

On Oct. 1, 1952, the department of anesthesiology at the Virginia Mason Hospital initiated a 24-hour record-keeping system of all obstetric anesthesias administered there that has continued to date. All anesthesias are administered by physician anesthetists, and these anesthesias and much of the obstetric data are recorded on a key sort-type record.[1] Most of the deliveries are performed with use of regional block procedures.

subclavius muscle. The patient in case 1 (table 1) had a small, poorly formed clavicle which was thought to be related to inferior embryonic differentiation of the primary ossification centers. It should be emphasized, however, that by far the most important cause of nonunion in the middle third of the clavicle has been improper initial operation.

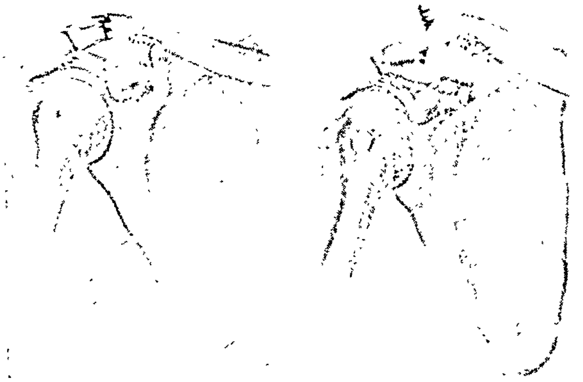

Fig. 1.—Fractures of outer third of clavicle with, *left*, coracoclavicular ligaments intact and, *right*, tear of coracoclavicular ligaments. Latter fracture is unstable and accounts for delayed union and nonunion in this portion of clavicle.

Pathological Findings.—Two distinct pathological types were seen. Type 1 was characterized by a false joint, with hyaline-like cartilage capping the dense bone ends, and possibly joint fluid. This was present in 10 patients. In the eight other patients the findings were quite different. These type 2 lesions consisted of resorption of the bone adjacent to the fractures, resulting in tapering bone ends, obliteration of the medullary canal, and a gap which was filled with fibrous tissue. These two distinct pathological types were best accounted for on the basis of infection or excessive bone removal in the second group. Surgical repair in patients with fractures of this type was more difficult because of the loss of bone substance. The gap was, at times, up to 3 cm. (fig. 2).

TABLE 2.—*Causal Factors in Eighteen Patients with Nonunion of Clavicle*

Site of Injury	Patients, No.
Outer one-third (4 patients)	
Tear of coracoclavicular ligament	4
Unconscious patient	1
Middle one-third (14 patients)	
Initial operation	10
Severe injury	10
Rotated fragment	2
Unconscious patient	1
Underdeveloped clavicle	1

In the case of outer third nonunions, the disrupted coracoclavicular ligaments became partially ossified (fig. 3).

Symptoms.—Weakness, pain, clicking, or deformity were usually great enough to cause th patient to desire repair of the defect. However seven patients were not sufficiently disabled to wis surgery. All female patients, with one exception sought correction; they were unwilling to accep the cosmetic defect, aside from other disabilitie Male patients were unconcerned with the appea ance but required relief of pain and fatigue. N instance of vascular or neurological impairment was encountered in this series.

Treatment

No difficulties were seen after repair of nonunio in patients with type 1 pathological findings. I these cases, good bone for securing end-to-end contact was present. Adequate length remained after freshening and opposing the bone ends, so that there was no tendency for distraction. Contact could be maintained easily. A minimum of 12 weeks is required for healing.

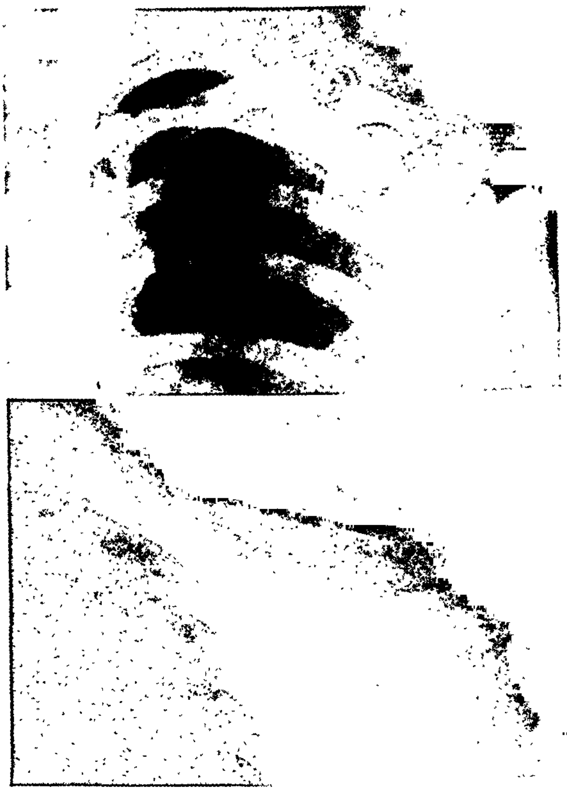

Fig. 2.—Pathological types of nonunion of clavicle: *top*, type 1, showing good bone length and false joint; *bottom*, type 2, showing resorption and tapering of bone ends. Note gap in second type.

Failure to regain bone union was limited to patients with nonunion of type 2. Repair was done in six of these and failed in three. In each failure (cases 12, 13, and 14), tibial or iliac grafts were used to span the gap, and contact of the ends of the clavicular fragments was not maintained. Furthermore, a greater risk of reactivation of infection was evidenced in the reconstruction of type 2 lesions. Nevertheless, when secure approximation of the ends of the clavicle was maintained by internal fixation for an adequate period, union occurred (cases 9 and 16). The resultant shortening did not produce brachial plexus or vascular pressure symptoms. In one instance, the subclavian vein was torn during the freeing of the bone ends, reminding us of the intimate relationship between this vessel and the scar tissue.

Fig. 3.—Ununited fracture of outer third of clavicle. Associated ossification of coracoclavicular ligaments depicts true extent of lesion.

It was consistently observed that wire loop suture alone could not control angulatory displacement of the clavicle. An intramedullary rod did not eliminate rotary movement and rarely prevented distraction. It was obvious that the patient could shrug the shoulder in a spica and that this form of fixation was also incomplete. In view of the difficulty of maintaining contact and alignment in those patients with lesions in which resorption was present (type 2), all three forms of fixation were required. However, patients with type 1 pseudarthroses could be treated adequately by simpler methods (fig. 4).

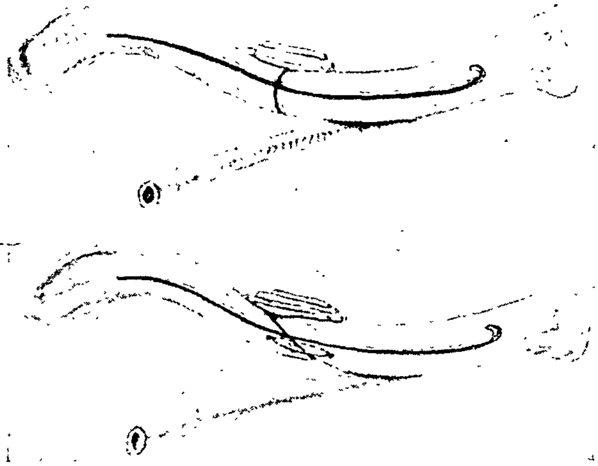

Fig. 4.—Repairs of middle third nonunion of clavicle. Ends of fragments are freshened. Intramedullary nails are inserted from medial to lateral away from subclavian vessels. Grafts are placed posteriorly. Type 2 lesions require wire loop suture to maintain contact and eliminate gap.

Patients with symptomatic outer third nonunions needed surgical repair rather than excision of the outer fragment, as has been recommended by some surgeons,[5] because the accompanying coracoclavicular ligament disruption allowed the stump of the proximal portion to be pulled upward, becoming prominent and requiring repeated excisions (fig. 5). Either the ununited fracture or the ligaments must be repaired, and the former is usually preferable (fig. 6).

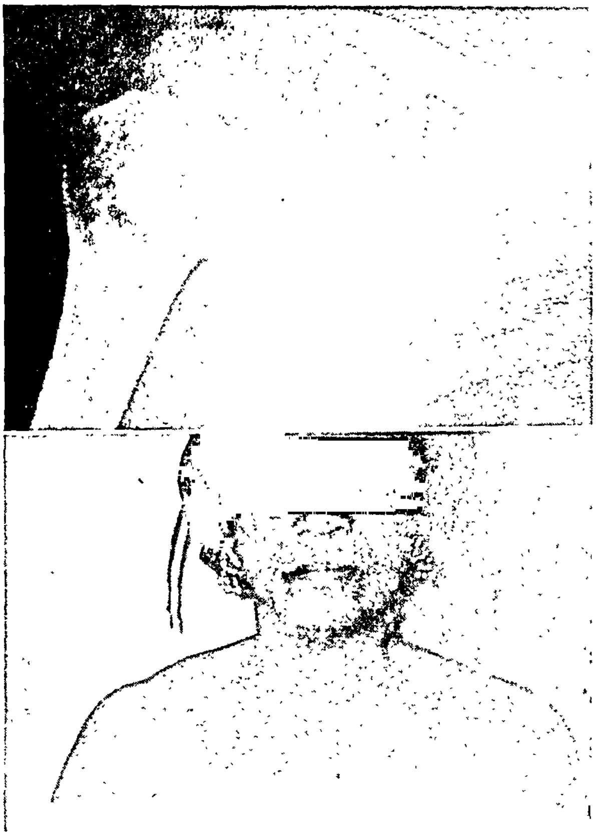

Fig. 5.—*Top,* error of excision of outer fragment for treatment of outer third nonunion. Disrupted ligaments allow clavicle to pull upwards. *Bottom,* patient's fracture required repeated excisions. If outer fragment must be excised, coracoclavicular ligaments should be reconstructed.

Excision of part or all of the clavicle was done in three patients with pathological fractures who are not included in this series. The results after these procedures indicated that loss of the clavicle weakened overhead hold and produced shoulder asymmetry. The result was inferior to that after repair. It was thought that this procedure should be used only for relief of brachial plexus or vascular symptoms or in selected patients with pathological fractures whose life expectancy is limited.

Nonunion of the Clavicle in Children.—Defects in children should be considered separately, because it is impossible to differentiate positively between congenital pseudarthrosis due to failure of development and traumatic defect. Three children under 12 years of age were seen who were thought to have ununited birth fractures. In each, the lesion was unilateral and had been noted for the first time when the child was 2 to 3 months of age, and the "tumor" increased in size as the child grew older. Roentgenography indicated middle third defects with ample bone substance and a false joint (fig. 7). There were no associated congenital anomalies elsewhere in the body. Repair was easily accomplished because there was adequate length. The embryologist[6] and radiologist[7] at our center believed that these lesions had the characteristics of ununited fractures rather than developmental defects. It therefore seems probable that they should be differentiated from neurofibromatosis or failure of development, especially because their prognosis after repair is so much better.

Comment

Open reduction and internal fixation constitute the preferred procedure in a few specific patients with clavicular fractures, e. g., those with fractures of the outer third associated with tears of the coracoclavicular ligaments, middle third fractures with rotation of a large intermediate fragment, soft tissue interposition, or vascular or brachial plexus compression. Operative treatment may also be necessary for immobilization in certain patients with multiple injuries or coma. It may even be justified electively, at times, on the basis of the convenience it might afford certain patients. However, the increased incidence of complications after elective surgery on the clavicle must be weighed in the decision, and, in any case, operative procedures must be done with greater care than they have been in the past.

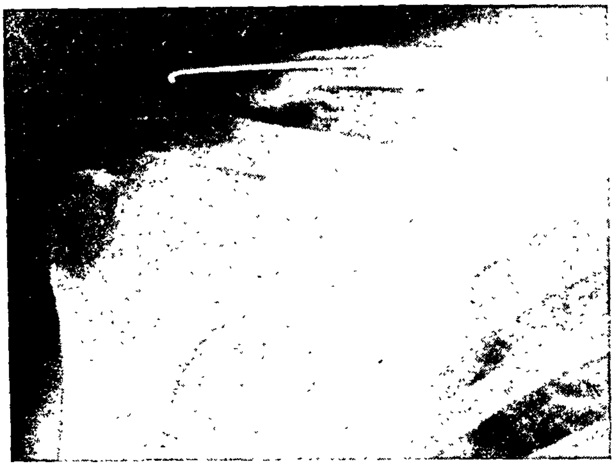

Fig. 6.—Repair of outer third nonunion. This is generally best accomplished by reestablishing bone union.

Summary and Conclusions

A series of 18 patients with ununited fractures of the clavicle is presented. Four fractures were in the outer third and 14 were in the middle third. The clavicle is not "invincible." Lack of immobilization, as in comatose patients, may result in nonunion. Delayed union or nonunion of fractures of the outer third is produced by the instability associated with tears of the coracoclavicular ligaments. Outer third fractures with concomitant ligamentous disruption are best treated by internal fixation, in distinction to fractures in which the ligaments are intact. By far the most frequent cause of nonunion of fractures in the middle third has been improper initial operation. Operation here must be done with the same regard for soft part attachments and fixation as in other open reductions.

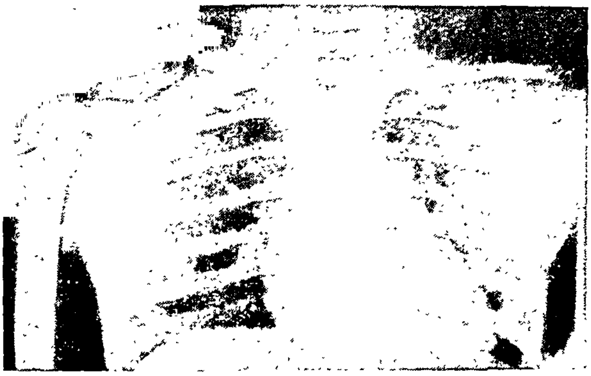

Fig. 7.—Probable nonunion of birth fracture. Although it is impossible to differentiate this from pseudarthrosis due to defective development, it seems probable that certain of these lesions, such as one shown, are actually ununited birth fractures.

Nonunion of the clavicle usually produces sufficient deformity and symptoms to require treatment. Treatment should consist of the reestablishment of bone continuity rather than excision, except when the lesion is producing pressure on the brachial plexus or subclavian vessels or in pathological fractures in patients whose life expectancy is limited. Bone union is more apt to occur if end-to-end contact of the fragments is maintained rather than the gaps bridged with bone grafts.

POSTPARTUM HYPERTENSION AFTER USE OF VASOCONSTRICTOR AND OXYTOCIC DRUGS

ETIOLOGY, INCIDENCE, COMPLICATIONS, AND TREATMENT

Gilbert N. Casady, M.D., Daniel C. Moore, M.D.
and
L. Donald Bridenbaugh, M.D., Seattle

In a study of 8,000 deliveries performed under continuous caudal block analgesia, the records of 741 women indicated that the combined effect of a vasoconstrictor and an oxytocic drug, given three to six hours apart, led to severe hypertension in 34 (4.6% of 741) patients. These findings suggest that the patient's need for prophylactic administration of vasoconstrictor drugs in conjunction with caudal block analgesia in obstetrics should be evaluated before giving them. Treatment with chlorpromazine hydrochloride, to prevent the severe and disabling complications of postpartum hypertension, is essential.
